**Education.**—Württemberg has always been one of the most enlightened countries in Germany; it has given birth to the most profound thinkers, to some of the greatest philosophers, and to a number of statesmen of Germany which have furnished so many eminent men to the public service as to constitute a national life as Württemberg. For this it is chiefly indebted to its good institutions for education, of which it probably has more than any other country of equal extent in the world.

There is not a parish without its school, and the number of children attending the schools is one in six of the entire population, a much larger proportion than in England and France. There is a university at Tübingen, with about 800 students, seven grammar schools, four gymnasiums, and twenty-eight Latin schools, one superior evangelical seminary at Tübingen, fifty-four inferior evangelical theological seminaries, four seminaries for Roman Catholic priests, one seminary for evangelical and one for Roman Catholic schoolmasters, twenty-four schools of philosophy and sciences, 1470 evangelical and 797 Roman Catholic parish or district schools, and others for particular objects, e.g. for the deaf and dumb, for the blind, for drawing, &c. According to law it is unlawful to be above the age of six years to that of fourteen, and afterwards to attend instruction in the Sunday-school to the age of eighteen. The private literary societies are numerous.

**Revenue.**—The finances are in a prosperous condition; the net revenue and positively known expenditure is something more than nine millions of florins, and the ways and means were calculated in 1835 to afford a small surplus of only 6000 or 7000 florins; at the end of the three years, in 1838, it was found however that the revenue had exceeded the expenditure by 4,731,000 florins, so that the government was able to take off some taxes and pay off a portion of the public debt. The debt amounted on the 30th of June, 1838, to 34,364,202 florins, almost the whole (23,350,000 florins) at par at interest.

**The Army.**—Every subject of Württemberg is liable to serve as soon as he has completed his twentieth year, and he has to serve six years. The army consists of eight regiments of infantry, four of cavalry, two battalions of artillery, two garrison companies, and a squadron of pioneers; in all 18,986 men, including 387 officers: this is the war establishment; but in time of peace only between 5000 and 6000 men are embodied.

**Constitution.**—Württemberg is an hereditary monarchy. The position of nearness to the existing constitution, which was happily completed in 1819 by the present king. His father had drawn up a constitution in 1815, and conferred an assembly of the estates of the kingdom, to which he presented it, fully expecting that it would be joyfully accepted. But circumstances having failed, he was obliged to leave the work unfinished at his death, in 1816, to his son and successor, who, for above two years, was equally unsuccessful, but in 1818 he was so fortunate as to agree with the estates on a constitution which has given general satisfaction. According to this constitution Württemberg is a constitutional republic, divided into the parts of the kingdom, with a diet or parliament, consisting of two chambers. The chambers have a share in the legislature, have the right of presenting addresses and petitions to the king, and of granting taxes. No law can be altered or abrogated without their consent. The king's person is inviolable. His debt is his government; but all his ordinances must be countersigned by the minister to whose department they relate, and who is responsible for them. The crown is hereditary in the direct male line, according to the order of primogeniture; the crown of the male line is the sole title to the succession of the crown. The constitution secures to the subject every reasonable degree of civil and religious liberty, Christians of the Lutheran, Calvinistic, and Roman Catholic faith being placed on a footing of perfect equality. The church was indeed much restricted, if not abolished, by a decision of the German diet of the 10th of October, 1810, to which Württemberg, as a member of the German Confederation, was bound to conform. Württemberg has the sixth place in the German body politic, and was one of the few constitutions of the Confederation which was not altered by the new constitution of 1813. Its contingent to the army of the Confederation is 13,995 men, viz. infantry, 11,856; cavalry, 1750; artillery, 724; with 24 pieces of cannon and 116 pontooniers. Its annual contribution to the chancery of the Confederation is 2000 florins.

**History.**—At the beginning of the fourth century the Alemanni appeared in the country, afterwards called Suabia, as successful and dreaded enemies of the Romans; but in 406 the Alemanni were overcome by the Franks of Clovis. This province, besides that, which subsequently belonged to the kingdom of the Franks, under whose kings it was governed by dukes. About this time Christianity was introduced into Germany (Alemannia). When Germany was divided by Charlemagne, we find Suabia under dukes, who were often changed; and, according to the policy of those times, the emperor's own sons were often put in their place. When the princes of the house of Hohenzollern, who had become dukes of Suabia, was in 1547 overthrown, the imperial estates of Suabia to be governed by members of their family. Philip laid the foundation for the decline of his house, since, in order to gain adherents as emperor, he sold and gave away a great part of the hereditary estates, and thus created a great number of petty princes. The part of Germany was in 1298 occupied by Charles of Anjou, who in 1295, in the acknowledgment of the family now on the throne. The accounts up to his time are little more than mere names, and so vague and uncertain, that it is not easy to understand them. Ulrich, who according to a tradition, was only 20 years of age, was the emperor in 1260, and left his dominions, considerably enlarged, to his two sons, of whom Ulrich II. died in 1279, and was succeeded by his brother Eberhard, who was a minor only fourteen years of age. Eberhard, who acquired the supreme power, was one of the most distinguished princes of his line, and his long reign was marked by great vicissitudes of fortune. The time at which these two brothers commenced their reign was that in which no law had any force but the right of the strongest (sua natura). This state of affairs corresponded to the restless and daring spirit of Eberhard, whose motto was, 'God's friend; everybody's enemy.' Above all he made the Imperial cities, which were rising in importance, feel the weight of his arm. He was always taking advantage of the unsettled state of the duchy to make himself independent; but their increasing wealth laid the foundation for that jealousy which, under the name of the 'War of the Cities,' continued with increased bitterness. When he died in 1319, after partial successes, he was on the point of ruin, when peace was brought about, in 1297, by the mediation of the archbishop of Mainz. Of his son Ulrich I. little is known, and all fresh disputes arose between him and the emperors Rudolph and Albrecht, which however were terminated by an amicable arrangement in 1394. The court—
suffered dreadfully by this continued warfare. On the death of Albrecht, in 1508, Eberhard was a candidate for the crown of Bohemia; but the princes, dread of his ambitious and rapacious policy, elected Henry, count of Luxemburg. The new emperor held his first diet at Speyer (Spire), and Eberhard was summoned to appear and answer the complaints of the Imperial estates. He appeared independently, with a suite of 200 horse, and withdrew, declaring that he was nobody's vassal. He was then put under the ban of the empire, and an army was sent to enforce the decree. Eberhard defended himself brantly, but his enemies were too strong for him. He was taken prisoner, and his dominions were reduced to a state of servitude. He was a year in prison, and then permitted to escape from the hands of the emperor. But Henry dying in 1513, Eberhard's enemies were discouraged, and with the aid of his brother-in-law he speedily recovered the whole of his territory. He was now as powerful as ever, and in the last years of his reign acquired considerable additions to his dominions. At the close of his life he got into a dispute with his brother-in-law, and a defeat experienced by his son in attacking the castle of Reichenberg hastened his death in 1525, after a most eventful reign of sixty years (i.e. from his father's death in 1433).

Eberhard's son, Ulrich III., was of a pacific temper, who however could not avoid some disputes with his neighbours. During his reign the country was afflicted with severe drought, storms of hail, and famines, and the plague (1423), a terrible calamity which greatly reduced the population of the duchy. All these misfortunes were ascribed to the Jews, who were cruelly persecuted. Ulrich made some important acquisitions of territory. He died in 1544, leaving two sons, Eberhard IV. and Ulrich IV. After ruling together for several years, Ulrich wished to have the country divided between them, which Eberhard wisely prevented; and Ulrich dying without children in 1566, Eberhard reigned alone. He was of the same warlike and enterprising spirit as his grandfather, and was obliged to end the ever-existing state of war by internal dissensions, by the intrigues of his enemies, and by the rivalry of Eberhard of Montmorency, who succeeded to the title of prince of the Palatinate. He was not a happy man; he possessed the power of a great prince, but his son died and left him without an heir. He was therefore obliged to declare his dominions a hereditary possession, and a regency governed till he was of age. The reign of Ulrich II. was not a happy one; the desolation of the Palatinate by the French and the Spanish succession caused the country to be repeatedly plundered by both powers. To defend himself he bought a great battery at the battle of Blenheim, but this did not save his dominions from further ravages; and after the conclusion of the peace, Austria, whose interest it was to have devolved himself, treated him with ingratitude, and at length, in 1612, he was compelled to sell his lands, which were given to Hanover. On his death in 1573, he was succeeded by Charles Alexander, who had distinguished himself as field-marshall in the Austrian service. This was a favourable circumstance, because the duchy was in constant feud with the kingdom of Germany by the French, who in fact sent an army over the Rhine under Marshal Berwick. The danger was happily averted. Charles Alexander had embraced the Roman Catholic religion, but he satisfied his subjects by the most solemn assurances that no change should be made in the reformed establishment. He reigned only till 1577, leaving three sons, all of whom in turn reigned after him. His eldest son Charles had only nine years of age, and was brought up from 1577 till 1617 with his brothers at the court of Frederic I. of Prussia, who gave promise of possessing all the qualities requisite for a good prince. He entered on the government in 1617, but he turned out a most extravagant and indolent prince, wholly negligent of his duties, engaged himself in an imprudent war with Denmark, and by the part he took with France against Frederic II. in the Seven Years' war. However, as he grew older he became sensible of his faults; on the fifty-four anniversary of his birth-day (Feb. 21, 1776) he acknowledged the mistakes he had made in a manifesto, and he declared that he wished to be real in the State, and was determined to reform himself. His brother Lewis, who succeeded him, was a highly-natured and kind-hearted man, but did not fulfil the expectations that had been formed of his talents. He died after a reign of little more than a year and a half, and was succeeded by his next brother, Frederic Eugene, who had gained great reputation in the Prussian army during the Seven Years'
ar. He was a man of talent, and well disposed to do

Very thing for the good of his country, but the French

olution, which had commenced three years before his

ession, was doubly fatal by causing Würtemburg to be

ately traversed by hostile armies, and by the propa-

gation of a revolution of which that country was a

outh. The French crossed the Rhine on the 24th of

une, 1796, and on the 18th of July entered Stuttgart;

nd the Austrians being obliged to retreat, the duke

 compelled to purchase peace with eight millions of francs

nd the garrison of Mannheim, which was in the midst of a

nsemble of the Estates, in March, 1797, to deliberate

 a the means of repairing the disasters of the country, but

e could not come to any agreement with them, and died

died apoplexy, on the 3d of June, 1797. He was suc-

ceeded by Prince William Charles, to whose

ife, in vol. x. of the 'Penny Cyclopaedia,' we refer for the

ferent events.

(J. D. G. Memminger, Beschreibung von Würzburg,

Stuttgart, 1857; Der Weimarsche Almanach; Brockhaus, Conversations-Lexicon; Hassel; Cannabich; Rea; Hirschelmann.)

WÜRZBURG, the capital of the Bavarian circle of the

lower Main, is situated in 49° 45' N. lat. and 9° 5' E. long.

This is one of the most important and populous towns of the

n valley of the Main; and the banks of that river, on

over which there is a bridge 200 yards long, adorned with

welve colossal statues of saints. A bishop's see was

established here so long ago as the year 741, and the bishops,

aving gradually obtained large grants, the dux, or the

dues, of the city, which extended to nearly 200 square

miles in extent, with 250,000 inhabitants, which formed the

principality of Würzburg. The revenues of the prince

bishop were 500,000 florins. As Würzburg has been for

100 years the head of a great state, and the bishopric has

formed the capital of a considerable principality,

conferred by a succession of 80 bishops, who were

princes of the empire, and by their power and wealth ex-

ercised great influence in Germany, we cannot be sur-

prised at the grandeur of some buildings, and churches,

which we find in this city. Of the churches which

remain, some are either incomplete or have been

injured by modern additions. The principal are, 1. The

Cathedral, said to have been originally founded in the

eighth century, but which was wholly rebuilt subsequently

in 1042. It contains many fine paintings, and a long

series of monuments of the bishops, each bearing the

word in one hand and the crozier in the other. The

chapel of Bishop Schönborn is very rich, or rather,

consists of a screen of marble and gilt.

2. The church of St. John in Hung, built on the model of

St. Peter's at Rome. 3. The New Minister, containing the

effigies of St. Kilian, one of the earliest preachers of the

gospel in Germany, and the Irish missionary, who was

the apostle of Franconia. 4. St. Mary's, an

elegant edifice, built in the years 1777 to 1749, in the true

German pointed style, with lofty lancel windows: and 5.
The University church (now closed), with the observatory

in its lofty tower. The most remarkable of our secular

buildings are, 1. The splendid episcopal palace, called

the royal residence, though rarely inhabited by the

royal family. It was built by two bishops of the name of

Schönborn, 1720-1744. It is an imitation of the palace of

Versailles, is 270 feet long, 30 feet high, and forms a

parallelogram with two projecting wings. It consists of

six quadrangles, and contains 254 rooms, and cel-

laring for 2200 tuns of wine. The grand staircase is cel-

ibrated for its magnificence and the elegance of its design.

The first floor is occupied, especially as the

emors on their way to Frankfort have fallen into decay

through neglect and the lapse of time. 2. The Julian

Hospital, a very large, wealthy, and admirably arranged

institution. 3. The town-hall. 4. The University, and

Clinical establishment, an anatomical museum, a collection of instruments, a

next library of 100,000 volumes, a cabinet of works of

art, &c.

The charitable and useful institutions are very nu-

nus, among them are a gymnasium, a seminary

for priests and schoolmasters, a veterinary school,

a polytechnic institution, a school of industry, a Sunday

school of design for mechanics and journeymen, schools

for the blind, for midwifery, for swimming, and four hos-

pitals, besides the Julian hospital already mentioned.

There are manufactures of all kinds, yet none on a very

large scale.

In the smaller division of the city, on the left bank of

the Main, there is a steep hill or rock, called the Fränk-

enburg, or Marienturm, about 400 feet high, on which the

citadel stands. It is pretty strong, and, together with the

portion of the city called the Main quarter, is capable of

standing a siege. The view from the citadel is very fine;

the city itself, with its numerous towers and steeples, has

the most striking appearance; and the bright Main, here

a considerable river, with numerous boats and barges, flowing

with many windings through the richly cultivated valley,

gives a charming variety and animation to the scene.

On the slopes of the hill of the Marienturm, on the

Leine, containing about 60 acres, grows the celebrated

Leisten wine, one of the very best sorts of Franconian

wine; and on the Steinberg, which is at no great distance,

grows the Stein wine (Stone wine). On the whole there

are, in the immediate vicinity of the city, 7,000 acres

of vineyards and many large gardens. Near the city is a

hill called St. Nicholas Hill, or the Chapel Hill (Kappellen-

Tberg), from a very handsome church or chapel, which is a

much-visited place of pilgrimage. On the ascent there

is a small church with the statue of St. Christopher, our

Saviour. The view from the summit is nearly equal to

that from the citadel.

The population of Würzburg is 25,000, besides the

garrison. The inhabitants derive some advantage from

the city being the seat of a seminary and several offices of the

circle, and the residence of the bishop and chapter;

but their subsistence is chiefly derived from their

gardens and vineyards. They have a considerable export

trade, by means of the productions of the city,

especially their highly estimable wine. (Brockhaus,

Conversations-Lexicon; Hassel, Erdk.

schreibung, vol. iv.; Stein, Geogr. Lexicon; Der Weimarsche Almanach; Murray's Handbook of Southern Germany; Brockhaus' Lexicon.)

WURZEN, a town in the kingdom of Saxony, is the

seat of a suffragan bishop, founded by Bishop Henry, in 1114,

in the circle of Leipzig, near the river Mulde, on the road

from Dresden to Leipzig, 12 miles from the latter city.

The principal buildings are: Cathedral, which contains

numerous monuments of the bishops; the church of St.

Wenzel; the palace, built in the years 1491-1497; the town-

hall and the chapter-house, in which the Protestant canons

meet every other year. Wurzen was unquestionably a much

more important place in the 17th century, for in this

century it has suffered dreadfully in the many wars which have de-

solated Germany in the last four or five centuries, but espe-

cially in the Thirty Years' War, when it was taken and

burnt, by the Swedes, who committed the most horrible barbarities and excesses. There are now nearly 4000 inhabitants, who gain their living by bleaching, weaving, knitting, and basket-making.

(Brockhaus, Conversations-Lexicon; Engelhardt, Vater-

landzunde.)

WYATT, SIR THOMAS, called 'the Elder,' to distin-

guish him from his son, the subject of the next article,

was born at Allington Castle in Kent, in the year 1503. His

father, Sir Henry Wyatt, the representative of a family

some consequence, originally from Yorkshire, appears to

have bettered his worldly fortune by attaching himself to

the rising fortunes of Richmond, afterwards Henry VII. He

was imprisoned in the Tower, in the last years of Richard

III., and treated with great severity. Immediately after

the battle of Bosworth Field, Sir Henry, who had

been early placed by Henry in situations of emolument,

for in 1493 he was able to purchase the castle of Alling-

ton. He was one of the executors of Henry's will, and

appears to have had a still greater fortune after the death

of the father. He obtained a grant of part of the

estates of Empson, the first that were forfeited to the

crown in the reign of Henry VIII. He survived till

1555.

Nothing is known of the tenor of Thomas Wyatt's life

previous to his being entered of St. John's College, Cam-

bridge, in 1515, when he was twelve years old. He took

his bachelor's degree in 1518, and proceeded to his Mas-

ter's degree in 1520. The next incident in his life, after

the knowledge of which has been preserved, is his participation

in a magnificent feat of arms performed before the king at
Greenwich, at Christmas, 1525. He was then one of the gentlemen of the king's household. He was married to Elizabeth, daughter of Brook, Lord Cobham. The year of his marriage is not known, but his eldest son Thomas was born either in 1521 or 1523. A long interval of seven years, entirely barren of events, succeeds. In 1531, Anne Boleyn came to live in the house of her uncle, and the next year, from Dover to Calais a short time before her marriage; and in July, 1533, we find him officiating for his father as one of the gentlemen of the king.

This meagre array of incidents merely indicates that Wyatt was a gentleman who had been well educated; early settled in life by marriage; and introduced at court under the auspices of a father who had influence enough to obtain for him appointments suited to his age. He had already obtained some reputation as a poet, for, in 1527, in some Latin verses addressed to him from Paris, compliments him on his compositions. In person he was strong, but elegant; with fine features, a penetrating eye, and a mouth of singular sweetness. He was dexterous in the use of arms; he sung plain well on the lute, and spoke French, Italian, and Spanish with fluency. His readiness at repartee is a constant theme of his contemporary elogists.

There is much perplexity in the accounts of the danger in which he was involved on account of Anne Boleyn. So contradictory are the statements, that it is impossible to decide at what time he was placed in peril, and whether as friend or foe of that lady. Fuller's "Sir Thomas Wyatt fell, as I have heard, into King Henry's disfavour about the marriage of Anne Boleyn, her cousin; and by his indiscre- tion, and discretion he extricated himself"—admits of either interpretation. Judging by Henry's character, it seems more probable that Wyatt fell into temporary dis- grace from having shown his aversion to the match, than from having been suspected of too much intimacy with the lady. Anne Boleyn, it may be observed, was executed in May, 1536; on the 18th of March of that year Wyatt was dubbed a knight by the king; and in 1537 he was with the king's sanction nominated high sheriff for Kent.

The remaining part of Wyatt's life was passed in the toils of diplomacy and anxieties of court intrigue. In April, 1537, he was appointed to succeed Peter as Henry's minister at the Spanish court. He remained at Madrid till the beginning of 1538. In May he was sent back to Spain (Bonner being joined in commission with him); in June he followed the emperor Charles V. to Nice on his expedition to meet the Pope and Francis I.; in July he was with the emperor at Paris; and in August at Barcelona. In April, 1538, he was sent to Antwerp, but was detained in Spain till June. The principal service he performed for his king during his Spanish mission was keeping him informed of the intrigues of the court. The indifferent reception that Cardinal Pole experienced at the hands of Charles V. at this time is attributed to the dexterous management of Wyatt. He had urgently solicited to be recalled for nearly a year before he could obtain his wish. His desire to return to England was excited in part by the necessity of looking after his family concerns, his father having died about this time; and in part by the necessity of being at hand to meet the charges brought against him by Bonner. The distaste he entertained for Spain was probably occasioned in a great measure by the anxious state of his mind. All his verses written at this time, whether descriptive or didactic, in business he employed himself in corresponding with his son, or in superintending the education of a young person of the name of Barker, recommended to his care by Wroth- esey, or in composing verses. He mixed little in society; his principal amatory verses were the ambassadorials to Venice and Ferram. He was not allowed to remain long unemployed. Towards the close of 1539 the emperor began his journey through Flanders down into the Netherlands. Wyatt was appointed ambassador-extraordinary to the imperial court, with instructions to join Charles on his road through France, Wyatt joined the emperor at Blois, on the 14th of December, accompanied him to Paris, and left that city on the same day with him (29th January), proceeding direct to Brussels, there to await his arrival. He continued in attendance on the court at Brussels and Ghent till about the middle of May, when he returned to England. Wyatt had zealously seconded Cromwell in promoting the match between Henry and Anne of Cleves. During his residence in the Netherlands he continued advising the policy of the emperor for the extension of the Protestant princes of the empire. By this course he ran counter to the inclinations of the king, and, in common with Cromwell, lost favour with him. Wyatt was made a privy councillor, but having been disgraced with the falsehood of the statement which he had to deal; but prudence had also a share in his resolution to retire from his diplomatic career. He was said that Cromwell's enemies were gaining the ascendency, and he felt that the fall of his patron was inevitable. Although neither allowed to cross-examine Bonner's re- nesses nor produce any of his own, he was acquitted for the month of June, 1541. On the 10th of July follow- ing he was granted a grant of lands in Lambeth from the king, but in 1542 he was created hereditary lord of the king's near of Maidstone; and in the same year he received additional valuable grants. These favours would seem to imply that Henry was convinced of his loyalty and satisfied with his services.

The brief remainder of his life was spent in retirement at Allington. He bes himself informed us that when the season permitted he was used to hunt and hawk; but as the depth of winter he was fond of shooting with his bow and arrow, and at all times of the year he devoted himself to study or the composition of verse. In October, 1542, he was unexpectedly summoned to meet the king, and, eager to show his zeal, overstrained himself in his hasty journey. He was seized in consequence with a fit of the dropsy at Sherborne, and died there on the 12th of the month.

Wyatt was one of the most elegant and accomplished courtiers of his age; and a statesman of great sagacity, dexterity, and integrity. There were four reasons, says Mr. Hawke, which rendered him extraordinary—first, his generous entertainment; secondly, his far- knowing discourse of Spain and Germany, so instinct with the interests that was his masterpiece, they hurrying he studied him for his own satisfaction, as well as for the exigencies of the times; thirdly, his quickness in observing, his civility in entertaining, and his readiness in encouraging every man's peculiar parts and inclinations; and lastly, the favour and notice with which he was invested by his king. He was an able, forward, and successful general. His amatory verses, as is now matter, much like other amatory verses. The language, though less fluent than that of modern bardsingers, who have a language made rhetorical to their hands, has been attributed to the death as one of those whose works mark the progress of the language. His satires have more of matter in them, and more of nerve in the variation. The first is remarkable as containing the earliest English version of the Two Country Mouse. Of Wyat's prose writings, his letters of state business show much shrewdness; his letters to his son exhibit a pure, elevated, and well disciplined mind. Take into account the time at which he wrote, his prose is always struck us as more to be admired than his verse. (Caley, "Life of the Earl of Surrey and Sir Thomas Wyatt the elder.")

WYATT, SIR THOMAS (the Younger), only son of the preceding, was born in 1521, or at the latest in June, 1524. He was married to Jane, daughter of John Hawkwood of his ancient house in Kent. He was born in 1527, when he could not have been more than fifteen or sixteen years old. It has been conjectured that his father was induced to settle him thus early in life with a view to grandeur, and that he was sent to a grammar school, and in November; and in November; and in November, and in November. The supposition is rendered plausible by the tone of two letters addressed by the father to the son a year or two before the marriage, which have been published by Mr. Not. In October, 1542, Wyatt succeeded to his father's estates; and before little more than a year had elapsed, executed a deed (discovered by Mr. Calamy in the Augustan Office), which further corroborates the suspicion of the wildness of his youth; an alienation of his estate of Tournay in Dorsetshire in favour of Francis Wyatt, his infant son.
by the daughter of Sir Edward Dorrel, of Liddelcote. In April, 1543, he had been imprisoned for assailing the earl of Surrey in broken words, the windows of the citizens of London at night with stones shot from a crossbow. Surrey gravely stated in after-life that his intention was, by frightening the citizens through the sudden and mysterious breaking of their windows, to turn them to repentance; but this ingenious defence, if alleged before the privy council, availed neither himself nor his accomplices Wyatt and Pickering. After his release from the Tower, Wyatt raised a body of men at his own expense, and did good service with them against suppressed rebels, as well as against the semi-religious ceremonies of Churchyard that the military talents of Wyatt were soon acknowledged. Early in 1545 he was placed in command at Boulogne, and constantly employed against the enemy in that quarter. When Surrey was appointed governor of Boulogne, in September, 1545, Wyatt was made one of his council. "I assure your majesty," Surrey wrote to Henry VIII. respecting Wyatt, "you have framed him to such towdardness of knowledge in the war, that he is not much like him in your realm for hardness, painfulness, and cir- cumspection, and natural disposition to the war." Wyatt continued to hold his situation at Boulogne after Surrey's recall, and even, it has been assumed, till the place was first attacked by the French in 1552.

During the latter part of the reign of Edward VI. Wyatt appears to have lived chiefly at Allington. The part he took immediately after the king's death is ambiguous. Sir John Bridges subsequently reproached him in words which seem to indicate that he was accused of having made Lady Jane Grey; but Wyatt in his defence before the privy council asserted that "he had served the queen against the duke of Northumberland, as my lord of Arundel can witness." An attempt to surprise Ludgate on the 7th of February failed, and he with one or two of his followers were separated from the body of his troops, and taken in Fleet Street. His conduct at the moment of his capture, as narrated by Stow, gives him the appearance of one who had completely lost his self-possession. He was not tried till the 15th of March, and he is accused during the interval of having implicated Elizabeth and other persons. Wyatt had been in the army during and after the granting some considerable advantages over the royalists. pushed out to Southwark. An attempt to surprise Ludgate on the 7th of February failed, and he with one or two of his followers were separated from the body of his troops, and taken in Fleet Street. His conduct at the moment of his capture, as narrated by Stow, gives him the appearance of one who had completely lost his self-possession. He was not tried till the 15th of March, and he is accused during the interval of having implicated Elizabeth and other persons. Wyatt had been in the army during and after the

Sir Thomas Wyatt appears to have been a zealous Protestant in theory, although religion does not seem to have exercised much practical influence on his conduct. In his youth he appears to have been wild rather than licentious. He was possessed of strength and address, and that kind of courage which carries a man with éclat through a body of nation, or after an hour's engagement. His tone when taken prisoner at Ludgate, and on his trial, was that of a man bewildered and borne down by his reverses. He does not appear to have possessed any of his father's literary talent. It is probable however that he had a considerable portion of his father's remarkable poetic talent. His name. His tone when taken prisoner at Ludgate, and on his trial, was that of a man bewildered and borne down by his reverses. He does not appear to have possessed any of his father's literary talent. It is probable however that he had a considerable portion of his father's remarkable poetic talent.

Wyatt, James, a very eminent architect, if not one of pre-eminent talent, notwithstanding that there is no memoir of him in Cunningham's 'Lives of British Architects,' and that his name has been omitted in a list of architects by a professional writer; for, deservedly or not, he certainly was celebrated among his contemporaries, and occupies a very conspicuous place in the history of the art in this country during the latter part of the eighteenth and the beginning of the nineteenth century. He was born in 1746, at Burton Constable in Staffordshire, where his father was both a farmer and a dealer in timber; and at an early age was introduced to Lord Bagnet, who determined to set out for Italy as an ambassador to the pope, took him with him, from which it is to be supposed that his lordship must have been struck by some symptoms of extraordinary talent, to take charge of a boy of fourteen in order to be employed upon building, which was finished and opened in 1772; but at once stamped his celebrity, and he thereupon became the 'fashionable' architect of the day. The Winter Ranelagh of the metropolis, as a whole calls it, was eminently attractive, and in a country, and itself the fashion and the rage as a place of amusement, was admired of course by all who pretended to taste or good breeding. It was fitted up in a style of grandeur till then unprecedented in this country, and was therefore eminently attractive. The object of the whole was to set Wyatt's Pantheon. There exist indeed views of the great room, or 'roundel,' but they are such that very little reliance is to be placed upon them; and even were they satisfactory in themselves, they furnish very imperfect Information: nor is more to be obtained from description, nothing deserving to be so called having been written at the time.

Generally as it was vitiated, and the name of his person, whether by the press or by the speeches of his friends, or by the character of mansions. Taken collectively, that class of his works afford stronger evidence of extensive practice than of superior talent. Considered individually, their architectural merit is of rather a negative kind. As houses they are commodious and handsome; but when looked at, they show themselves to be the works of an able builder rather than an architect, and exhibit far more of clever mannerism and of uniformly respectable mediocrity than of design. They are built on lines of the designs of the same design. James Wyatt was a degree or two less frivolous than Adam, yet hardly more distinguished: nevertheless it must be acknowledged that we are greatly indebted to both of them, if not for the taste, for the character of their buildings, and the refinement of their interiors, which they introduced into our domestic architecture. Wyatt's Grecian style, admired in his own day for its then almost proverbial 'simplicity' and chasteness, now strikes me as being very justly admired, and the modern taste, which is deficient in that artistic simplicity which results from uniform finish throughout, perfect harmony of character, and unity of expression. There is more of the prettiness than of the beautiful, of the neat than of the elegant, of the simple than of the ornate, in his so-called Italian style; nor could it perhaps be better described than as a sort of genteel commonplace. Probably he would have done more in his art had he been employed on fewer works, for the multiplicity of his professional engagements.
prevented him from bestowing much study on the respective designs. It has been recorded of him as matter for admiration that he was in his leisure hours at improving his designs while travelling in his carriage to the places he was about to be employed at; no wonder therefore that so many of them present such sameness and poverty of ideas, and no one little thing, being more than a few hasty sketches, with hardly any revising.

Accustomed to this specious commonplace and indelent fertility, he could scarcely rise above it on occasions which either demanded or afforded opportunity for achieving something noble. His attempt at Downing College, Cambridge, where however he was not eventually employed, was animadverted upon in a letter from Mr. T. Hope to the architect himself, as being altogether unworthy of the occasion. Neither did Chiswick inspire Wyatt with any kindled feeling for though the wings which he added to the house rendered it more commodious as a residence, they sadly marred its original grace as a finished gem of Palladian architecture.

About the time of James Essex's death (1784), the only architect of the period who had shown any knowledge of Gothic architecture in regard to its details, if not its principles, Wyatt began to turn his attention to that style, which he studied in the original examples. There was indeed hardly any other course to be pursued, for it was at that period there were no textbooks, as at present, to initiate the student into, and facilitate his progress by exhibiting specimens of it in all its manifold varieties. What architects of the present day find delineated and measured for them on paper, and are therefore enabled before they can have time to measure for himself; it is therefore highly to his credit that under such circumstances, and amidst so many other avocations, he gained the insight into it which he did; and that he attained to correctness in his details and individual forms, though not to a clear perception of the spirit and true character of the style. Very great allowance is therefore to be made for him, and it is most ungenerous to call him, as one who is himself distinguished by his knowledge of that style has done, 'James Wyatt of execrable memory.'

His first essay in that style was Mr. Barrett's at Lec near Canterbury (1783), and it was for the architect as happy a hit in its way as the Pantheon had been. Extolled by Horace Walpole, it served to bring the neo-Gothic to vogue for a time, some style of Gothic comparatively pure for the time, yet what now would be termed 'mongrel,' correct in particular features and details—even those however too ecclesiastical, ill applied, and put together without regard to propriety of character. From this, however, he soon became the exponent of our early Gothic architecture, as he and Mr. Milizia, that eminent architect, were so far from displaying any predilection for connected with his future profession, that he was bent upon going to sea, and made two attempts to do so, the first at the age of twelve, the second about three years later, on both occasions he was brought back. At the age of seventeen he was to have gone out with Admiral Kempenfeld, in the Royal George, but being prevented from joining the vessel in time he returned. He at length betook himself to the metropolis in the hope of finding some opportunity of entering into the naval service, but as the American war had terminated, no such opportunity offered.

These disappointments however were all so many steps of good-fortune, which reserved him for higher distinctions than he might else have obtained, even had he resided at some high post in the navy. He was not left a friendless adventurer in the metropolis: his uncle Samuel, who felt for his nephew Wyatt in 1792, as much as he disapproved of the Trinity House (which willed it to the metropolis in the hope of finding some opportunity of entering into the naval service, but as the American war had terminated, no such opportunity offered.

These disappointments however were all so many steps of good-fortune, which reserved him for higher distinctions than he might else have obtained, even had he resided at some high post in the navy. Wyatt then offered to him a place in the American theatre, which he received with some desire to accept it. However he was not long seated there, for the following year West was re-elected.

After this, scarcely any particulars have been recorded of his life, although materials for a full professional biography of him may possibly be in existence. He himself has left none by publishing any of his numerous designs, whereby authentic memorials would have been preserved to us of the great hand with which he worked. Of Fonthill we have illustrations in two works, the one by Boswell, the other and more complete one by Rutley; yet both together do not afford that satisfactory architectural information which a complete plan of his designs or buildings. Of these last we subjoin a list, which, though scanty and imperfect, may be found convenient as far as it goes, notwithstanding that several design require to be supplied. 

Wyatt died September 5th, 1813, in consequence of being overturn in a carriage whilst travelling from Bath to London. He left a widow, who survived him till January 27th, 1817, and four sons, one of whom, Benjamin, was the architect of the Pantheon in London. Notwithstanding that he had a very extensive and lucrative practice, James Wyatt was so far from accumulating a considerable fortune, as it seems in the profession have done, that he was often involved in pecuniary difficulties, which may have been one reason why he did not care to incur the expense of engraving any of his designs or buildings. Of these last we subjoin a list, which, though scanty and imperfect, may be found convenient as far as it goes, notwithstanding that several design require to be supplied. 

1770-2 Pantheon, Oxford Street, London (burnt down January 14th, 1792).

1778 Doric Gateway, Canterbury Court, Cheapside, Oxford.

1780 Loo, in Kent.

1786 Observatory, Oxford.

1788 Library, Oriel College, Oxford: Ionic.

1789 Salisbury Cathedral: alterations.

1790 Balliol College, Oxford: alterations.

1791-2 Royal Observatory, Greenwich.

1796 Military Academy, Woolwich: castellated.

1797 Designs for alterations at Magdalen College, Oxford.

1800 Windsor Castle: alterations.

1802 House of Lords.

1805 Cashibury.

1831 Ashridge.

1847 Grammar school at Kew, now demolished.

Mausoleum at Chobham, Kent.

Mausoleum at Brockley, Lincolnshire. (Gentleman's Magazine, 1813; Creasy's Translation of Milizia; Pictorial History of England, MS. Mr. Wray.)

WYATTVILLE, SIR JEFFRY, nephew to James Wyatt, [WYATT], and son of Joseph Wyatt, who was born at Bent- upon-Trent in Staffordshire, August 3, 1766, at the free school of which place he received his education. He afterwards entered the school of the Royal Academy, but was so far from displaying any predilection for connected with his future profession, that he was bent upon going to sea, and made two attempts to do so, the first at the age of twelve, the second about three years later, on both occasions he was brought back. At the age of seventeen he was to have gone out with Admiral Kempenfeld, in the Royal George, but being prevented from joining the vessel in time he returned. He at length betook himself to the metropolis in the hope of finding some opportunity of entering into the naval service, but as the American war had terminated, no such opportunity offered.

Wyatt's disappointments however were all so many steps of good-fortune, which reserved him for higher distinctions than he might else have obtained, even had he resided at some high post in the navy. He was not left a friendless adventurer in the metropolis: his uncle Samuel, who feel for his nephew Wyatt in 1792, as much as he disapproved of the Trinity House (which willed it to the metropolis in the hope of finding some opportunity of entering into the naval service, but as the American war had terminated, no such opportunity offered.

tunities seem to have been held out to him at that time from that quarter; for in 1790 he accepted the proposal made him by an eminent builder (Mr. John Armstrong) who had extensive government contracts to join in business with him.

The line of business he now engaged in was highly respectable, nor the less so because eminently lucrative; still it proved for about twenty years a bar to his admission into the Royal Academy as a member of that body, nor perhaps for another reason, that it might be supposed to prevent his being employed very extensively as an architect by many noblemen and gentlemen in various parts of the country, either in improving and making additions to their mansions or creating new ones. Nearly all his works are of the eighteenth century, and from the fact that the exception of the new front of Sidney Sussex College, Cambridge (1833). He was not therefore so much known by repute to the public generally, as he might have been, had he been employed on buildings more to the taste of the time.

It seems to have been unexploited by himself when he was summoned to Windsor by George IV. in 1824; and perhaps it occasioned some surprise in others, when it was first announced that Mr. Jeffrey Wyatt was to be the architect employed in remodelling the Castle—though it may be said that the display of talent as had not till then been offered to any one in the profession for full a century. Important as that work, and great as was the celebrity derived from it to the architect, we need not enter into any account of it. It is said that Sir Jeffrey had a widower, his wife (Miss Sophia Powell) in 1810; and of their three children, Augusta, the youngest and favourite daughter, died at Windsor, in 1825; and George Geoffry in 1833; Emma, the eldest, survived him.

It was the architect's good fortune to behold his great work brought to completion by himself, and it was his intention to publish the designs, which he directed to be done by his executors, under the superintendence of a trustworthy architect. He executed the work and brought it out on a magnificent scale in two volumes, large folio, 1841, and forms, as regards the exterior of the Castle, the most complete and elaborate series of illustrations ever published of any building in the world, but is not so well known as it deserves, inasmuch as the view of the place, there is nothing to afford any information with regard to the interior, which, if not exactly what Sir Jeffrey wished to make it, contains much that would have been interesting both to professional men and the public, present or absent, being, with a like a satire upon the taste of his royal patrons, if not much himself, for in the interior of such a palace there ought to be a great deal worth exhibiting and worth studying.

It is further to be regretted that of his other works no authentic illustrations have been published in any opportunity. This work was not only brought out on a magnificent scale in two volumes, large folio, 1841, and forms, as regards the exterior of the Castle, the most complete and elaborate series of illustrations ever published of any building in the world, but is not so well known as it deserves, inasmuch as the view of the place, there is nothing to afford any information with regard to the interior, which, if not exactly what Sir Jeffrey wished to make it, contains much that would have been interesting both to professional men and the public, present or absent, being, with a like a satire upon the taste of his royal patrons, if not much himself, for in the interior of such a palace there ought to be a great deal worth exhibiting and worth studying.

tone of that court certainly did exercise considerable influence on the mind of Wycherly, for during his residence in France he solemnly abjured the Protestant faith, and was received into the bosom of the Roman Catholic church.

On his return to England, Wycherly was entered as a student of law in the Middle Temple. It would appear, however, from a passage in Wood's 'Athenea Oxonienses,' that he was previously sent for a short time to Oxford to be educated in the Anglican school. At that university he 'wore not a gown,' only lived in the lodgings of the provost of his college, was entered in the public library under the title of Philosophus Studiosus, in July, 1660, being then about 20 years of age. He departed without being qualified for a degree in any manner, having been by Dr. Barlow reconciled to the Protestant religion.

It is not easy to trace with certainty Wycherly's career from 1600 till 1669 or 1670, when he produced his first play. The accounts of his association with Charles II., intrusted with the Duchess of Cleveland, his introduction to Buckingham, and his intimacy with Rochester, are all derived from conversational gossip. It is sufficiently apparent however that he possessed means which enabled him to mingle with the gay world on a footing of equality, and that, forgetting of the lessons of the 'petite cour savante et prude,' he conformed to the manners of the time. Major Pack states that the family estate was worth 600£ a year in the time of Wycherly's father.

The first play, 'Love in a Wood, or St. James's Park,' was produced after May, 1669, and before November, 1671, with a success which enabled him to take rank as one of the leading wits of the day. His other three plays were all equally fortunate. The Gentleman Dungmire—published in 1671; the Plays Dealer in 1674; and the 'Country Wife' in 1678. The plays however appear to have been composed some time before they were acted—in 1669, 1670, 1675, 1671. There is much in these productions more of a man of the world than of a poet, and their vigour, their licentiousness will prevent their ever again becoming popular. The impression produced upon Wycherly by the severe documen of the Duchess of Montausier's court had been completely obliterated, and his whole life more or less occupied with an unsatisfactory and consecutively mingled. But his intellect, though familiarized with impurity, had not been enervated. He had a strong and just perception of character, and expressed it with vigour and felicity.

Several years after the appearance of 'The Plain Dealer,' Wycherly encountered the Countess of Drogheda, a young, rich, and beautiful widow, at Tunbridge. They met in a bookseller's shop. The lady came to inquire for 'The Plain Dealer,' and the master of the shop presented Wycherly's copy. The lady seeing the real play must have been subsequent to June, 1679, when the earl died. They were soon after privately married. The lady was (probably not without good reason) distractedly jealous. Dennis reports that the lodgings were in St. James's Park, the Garden, opposite the Cock Tavern, and that if at any time he entered that place of refreshment with his friends, he was obliged to leave the windows open that she might see there was no woman in the company. Of course a person of this disposition would feel considerable reluctance to trust her husband at the court. The unfrequency of Wycherly's appearance there gave umbrage, and lost him the favour of Charles.

The Countess did not long survive her marriage. She seems to have expired about 1680, and there is not an indication of the place of her burial that has come to light. Her last husband was a rich and high rank, and his death must have been an event of much public interest. The last time that he was heard of he was in France, and the probability is that he died there. It is also surmised that he was averse to his wife's imprudence, and that the solicitation of the latter was the only cause of his marrying her. The subsequent history of Wycherly is more likely to have attracted to him the munificence of James.

Wycherly did not profit by the king's liberality to the full extent, for, ashamed to confess the amount of his debt, he avoided the commission dropped by the Revolution. His father's estate, to which he succeeded some years later, was strictly entailed, and the income was attached by his creditors. A more decorous, if not a more virtuous generation had risen up, and Wycherly's state of wit was no longer the fashion. He continued to struggle with his difficulties till 1715, the year of his death. Eleven days before his death he married a young woman with a fortune of 1500£. What attractions such a match could possess for the lady is difficult to imagine. He contrived to spend a good deal of her money; but repaid her on his death-bed by the advice, 'not to take an old man for her second husband.'

In 1704 Wycherly published a volume of poems, to which he prefixed an engraving from his picture painted by Sir Peter Lely in the prime of life. Below this portrait was the inscription—'The best of English Poets—Wycherly.' A volume of poems, and 'moral reflections,' which he had in part prepared for the press, was published posthumously in 1725, by Major Pack, who prefixed a very short and meagre memoir of the author. Wycherly's poetic style is defective, and his moral reflections are a confusion of what is properly called feeling in them; but they are not unremarkably characterized by his vigorous common-sense. Some of his 'moral reflections' are terse and pointed.

Major Pack's 'Memoirs of Wycherly, from Dennis's Letters; Biographia Britannica; Leigh's biographical notice of Wycherly in Moxon's edition, at the review of the notice in the 'Atheneum.'
dican Orders about the year 1360. The fact may be so, but the earliest testimony to it, we believe, is that of Anthony Wood, who may have derived his knowledge from the records of the university of Oxford. There is no positive case of the subject among the extant writings attributed to Wycliffe. Dr. J. B. Bury (Papers and Records, vol. i., p. 303), and his avowed copyist Mr. Le Bas (in the 'Life of Wycliffe,' ed. by Mr. J. B. Vaughan, vol. ii., ed. 1828, vol. ii., p. 303), has the Archbishop of Canterbury, and the theological chair of Oxford. The matter is more correctly stated by Lewis, who says that 'he now publicly professed divinity and read lectures in it.' This he did, and assumed the name of Wycliffe, and took his degree of Doctor of Divinity, and became the leader of the anti-Roman party in the university of Oxford. The sentence is not so clearly proved as alleged to be sent by Edward III. to Pope Gregory XI., then residing at Avignon, to treat with his holiness about the practice of papal provision and other abuses against which the English parliament had recently passed several laws and resolutions, more especially the statute 35 Edw. III. 35. The very language of the statute as Wycliffe's name stands second in the royal commission (the first name being that of John, bishop of Bangor) may be taken as attesting the high public reputation to which he had attained in the court, especially the court at Bruges; the negotiation resulted in a very partial mitigation of the evils complained of; but Wycliffe is supposed to have had his aversion to the then prevalent ecclesiastical system considerably sharpened by his experience of the papal court. It is possible however he did not deem it necessary to declaim what of his advantages might fall to his share. Either while he was still abroad, or immediately after his return home, he was presented by the king to the prebend of Asl in the Collegiate church of St. Mary, in the diocese of Worcester: the latter date of ratification was 6th November, 1375. And about the same time he appears to have been also presented to the rectory of Lutterworth in Leicestershire, the right of nominating to which had fallen for his own to the crown, on the death of John Hoby, fellow of New College of Groby, the patron. Lewis thinks it probable that Wycliffe now left Oxford, or at least was at Lutterworth during the vacations. 'Here,' he says, 'as it appears to me, he first assumed the name of Wycliffe, and took the office of a very diligent and edifying preacher, since he preached not only on Sundays, but on the several festivals of the church, and of a most exemplary and unwaried pastor.' There are about 300 of his parish sermons extant.

He now however began to speak his sentiments very openly on the subject of the pope and the church. Lewis quotes him as in one of his writings or lectures soon after his return to England styling the pope 'Antichrist, the pope of Rome, and the moneymakers, clippers and purse-keepers.' The consequence was, that in a convocation of the clergy, held on the 3rd of February, 1377, a citation was directed to be issued for his appearance at St. Paul's on the 19th of the same month, to answer the charges of being an heretic and of publishing certain heretical or erroneous doctrines. Lewis appears clearly to have been the first to have happened in 1378. Wycliffe presented himself on the appointed day; accompanied by John of Gaunt, duke of Lancaster, and the Lord Henry Percy, earl marshall: a violent altercation immediately arose between these noblemen and Courtenay, bishop of London; the crowd, which was very great, broke out into a tumult; and the result was, that Wycliffe was dragged from his pulpit and carried into the street. The mob seems on this occasion to have sided with their bishop against Gaunt and Wycliffe.

A story told by Dr. Vaughan about a reference made to Wycliffe by the first parliament of Richard II., which met in October, 1377, on the subject of the right of the kingdom to retain its treasure, when required for its own defence, although demanded by the pope, and about a vindication of that right which he thereupon drew up, appears to be indifferently supported. It rests, we believe, on no better authority than Dr. Fox's 'Acts and Monuments.' Wycliffe may have drawn up some such paper; but probably not in answer to an application from the parliament. Be this however as it may, the protest against him for his doctrine, and the step which was then taken, were more formidable shapes. On the 5th of May 1377 (not the 11th of June, as Mr. Le Bas states), M. Cardinal Junius, a bull was addressed to Pope Gregory by the archbishop of Canterbury and the bishop of Lincoln, and others dated the same day to the king, requesting his favour and assistance in the matter of the removal of Wycliffe from Oxford, desiring them to withdraw the protection which they had given to the accused theologian. Before the 13th of May 1377, when it was feared they would not come down to Westminster, King Edward was dead, by Archbishop Sudley's mandate the pope was demanded to present himself in the church of St. John the Baptist in the 30th court-day from that time. The fact of his history that is ascertained is his appointment, in July, 1374, as one of the members of a
the following year, 1378, before a synod assembled, not in St. Paul's, but in the archbishop's chapel at Lambeth. This new attempt to put down the reformer however was not more successful than his former; the Londoners, if we are to believe the chronicler Walsingham, upon whom we are principally dependent for our information as to what took place, showed themselves disposed to take part with Wycliffe, and, breaking into the chapel, threw the bishop's body from his pulpit to the floor. He and his soner was secured by the arrival of Sir Lewis Clifford with a message from the king's mother positively prohibiting them from proceeding with the cause. He was let off with a simple admonition to abstain from repeating the objurgations against each other, and the safety of the notorious and avowed heretic, for which he had been transferred to Oxford with a dangerous illness, from which however he recovered. Soon after he got well he is supposed to have published his tract entitled 'De Papa Romano,' or 'Schima Don,' still preserved in MS., in which he made a scathing attack upon all kings throughout Christendom to seize the opportunity sent them by providence of bringing down the whole fabric of the Romish dominion, seeing that Christ had cloven the head of Antichrist and made the two parts fight against each other. This was followed by another writing, both in Latin and English, of which by far the most important was his translation of the whole Bible from the Latin Vulgate, being, it is commonly believed, the first complete English version of the Scriptures which had appeared. He considered it his duty to believe that this great work was finished, and several transcripts of the whole made and dispersed, some years before the death of Wycliffe; but it is probable that it was not all executed by himself, although it may have all undergone his revision.

It was inexplicable how such a work could have been brought upon Wycliffe and his novel opinions by the great outbreak of the Commons, Watt Tyler's insurrection, in 1381, which it was natural enough for the friends of the established religion to affect to refer, in part at least, to the destruction of old customs and the breaking up of all reverence for the authority, which, and his followers had laboured to produce. For Wycliffe, it is to be noted, while he himself remained stationary at Lutterworth or Oxford, preaching or lecturing there, had numbers of disciples whom, under the name of 'poor priests,' he was the forerunner of the modern bishops of the crown, and professed that the 'whole power to care for were basely and falsely ascribed to him by the malicious ingenuity of his enemies.' The two confessions are entirely different. His apostol and admirer, Mr. Le Bas, describes the one in English as a 'strenuous and spiritless examination of all reverance and authority,' while the other, in Latin, is a more systematic examination of the question of transubstantiation, not apparently without a deviation from the common faith as possible. The second given by his enemy Knighton is, that he laid to the audacious bearing, put on the breastplate of dishonor, attempted to dismiss his extravagant and fantastic ideas and prophecies as the productions of a man of learning, who was and professed that the former sentence was pronounced by the bishop of Oxford, but that soon after letters were obtained by the king in which Wycliffe was dared to teaching any longer in the University. This at last in May, 1382, a year after the death of Wycliffe, it is supposed by the execution of the sentence, murder, and by the end of 1382, the name of the archbishop of Canterbury, was touched with the name of the archbishop of York, his entire life is thus described by the biographers.

Wycliffe is supposed to have spent the remainder of his life in his parish of Lutterworth, where however his parish was more active than ever. Indeed the literary prophecies which he is commonly supposed to have written after this date are not without some probability. They are cuttinecred in the circumstances. It is related that some time after he was driven from the University, and sent to Rome to answer the charge of heresy, he wrote a letter to the Pope Urban VI., which appears to rest on nothing but a mere conjecture, addressed to his holies, published by Lewis from a MS. in the Bodleian.
in which he says, 'If I might travel in my own person, I would, with God's will, go to the pope.' But Christ has need ed me to the contrary, and taught me more obeisance to God than to man.' It is supposed that he had an attack of paralysis before this time. He recovered par tially, but found it necessary to hire another priest, John Purneye, to assist him in his parochial duties, and also to act as his amanuensis. At last, while he was in his church hearing mass, on Holy Innocents' day, the 29th of December, 1705, a brick was thrown down upon him, and he was thrown down by another violent fit of palsy, and he never spoke more, but died on the last day of the year.

In the obscurity in which much of the history of Wycke lies buried, it is difficult, if not impossible, to arrive at any certain conclusion as to the real character of the man and the motives by which he was actuated. He was probably honest, as far as honesty consists in sincerity, and he may have been ready to make any sacrifices for the good of his cause. It is also possible that he was scarcely called upon to make any; he continued to the end of his life in the enjoyment of considerable pre emptions in the church which he professed himself anxious to pull down; and in his attacks, both upon the mendicant friars, and, in addition to them, upon the other heads of the clergy, who fell under his lash, he evidently gratified his personal resentments, as well as maintained what he believed to be the cause of reason and true religion. Whatever other Christian qualities he may have possessed, his borough had suffered too little of Christian meekness or charity. His intolerance and violence, and even his coarseness of invective, are unmeasured. As for the particular opinions which he held, it is not quite easy to say what they really were. Certainly it would be strange if he did not hold principles probably different at different times of his life; secondly, we are by no means certain whether many of the writings attributed to him are really his. But generally his views appear to have resembled those of Calvist and presbyterian views; and some of the pamphlets published during his life time were very bitter, and strongly opposed to every great leader of the Reformation of the sixteenth century.

To some of the more peculiar doctrines of the Roman church he seems to have adhered to the end of his life: it may be doubted, for instance, if he disapproved of either the images on the church buildings or of the papal power. He evidently believed in the last; and, what is not very easily reconciled with his repeated denunciations of the papal power as Antichrist, he addresses Pope Urban in the letter mentioned above as the greatest of Christ's views upon, with, and in the other of his persons this pope, and he has been written shortly before, that entitled 'On the Truth of Scripture,' he describes it as being nothing less than paganism for a man to refuse obedience to the apostolic see. In his doctrinal theology he was a strong presbyterian and a strong Calvist, and not especially a presbyterian. Under the care he was independent and voluntary of the most extreme description; opposed to episcopacy, opposed to establishments, opposed to endowments, holding that the clergy should be supported only by alms, and that every man should be able to support a clergyman himself.

In the maintenance of those opinions his earnestness and passion and the dexterity of his logic are far more remarkable than any impression he leaves of solidity of judgment, or of a considerate and reflecting mind. Nor is his style any grace, or other attraction, except its occasional energy or vehemence. Of his writings, the fullest catalogue that has been attempted is that given by Dr. Vauughn (vol. ii., pp. 411-431), which is copied by Mr. Le Neve to the borough, is but a thin book, and not very government he was an independent and voluntary of the most extreme description; opposed to episcopacy, opposed to establishments, opposed to endowments, holding that the clergy should be supported only by alms, and that every man should be able to support a clergyman himself.

somewhat semiterete and rather contracted at the margins, furnished with 5 filiform thickish obtuse ribs at equal distances, and the furrows between these ribs furnished with a single serra; the commissure is narrow and has two sertae; and the vittae very narrow. There is but one species of this genus, which is a native of the West Indies at Puerto Rico, where it is cultivated with Musa paradisiaca and Lepidium virginicum. It is a smooth plant, with a terebra branched erect stem about a foot high, with terete leaves, much larger and flatter than the flowers. According to Koch, it has an affinity with Parley (Petroselinum) and fennel (Foeniculum), but differs from them in the petals ending in tapering points. The rays of the umbels are from 12 to 14 in number, and the leaves are stiff. It is called, from this, common parsley, and is furnished with a number of seeds, the one being roundish, the other oblong or oblong-obovate. It grows, however, in some quantity in Calais, probably in quality of public notory, where its treaty of Bretigny was solemnly confirmed by the oath of Edward and King John of France. Numerous similes, preferments in the church, for which we must refer to the elaborate detail given in his biographer, being determined upon him in the course of the next three years. By 1363, moreover, he had been appointed to the abbey warden and justiciary of the king's forests on the Trent. On the 14th of March, 1364, he had by order of the king an assessment of twenty shillings on the chequer. On the 11th of May, 1364, he was made keeper of the priory seal, and soon after he is styled secretary to the king, or what we should now call principal secretary of state. He was a close friend of the king, with the chancellor, the treasurer, and the earl of Arundel, to treat of the ransom of the king of Scotland (Raw, taken at the battle of Neville's Cross in 1415), and belonging of the truce with the Scots. And not least among his duties was this one, that he administered the oath of the priory council and governor of the great committee phrases however Lowth supposes do not express the office, but only the great influence and authority which had in those assemblies. There are several obituaries performed, both ecclesiastical and lay, of the time of Wykeham's death, and all of them say he is said to have held; but I do not mention these, because the authorities produced for them are such as do not entirely depend upon. And, as to his ecclesiastical benefits already mentioned, the practice of conferring, both ecclesiastical and lay, on him for the sake of the church by the king, is without doubt a matter of public interest, and to the elaborate detail given in his biographer, being determined upon him in the course of the next three years. constituting his successor in the chancellorship, and seems to have for years after this to retain both the favour of the king and the good will of the parliament, and even to have remained in habits of intimate and confidential connection with the Duke of Lancaster, to whose influence the removal of the clergy from the offices of state is said to have been owing.

At this time the bishops of Winchester had no fewer than twelve different castles or palaces, all furnished and maintained as places of residence. Wykeham's first undertaking was to find himself in possession of the see was to set about the task of founding colleges. This cost him above 20,000 marks. He also applied himself with great zeal and diligence to the reformation of abuses in the monasteries and religious houses of all sorts. A charter was granted to him, besides, at Sparkford, near Winchester, founded, in 1332, by the famous Bishop Henry de Blois, brother to King Stephen, in particular engaged much of his attention, and the objects of the charity were indebted to his persevering exertions for the restoration of many rights and liberties which they had originally enjoyed, but of which they had been for a long time defrauded. But the object which from the first chiefly occupied him was his own great foundation of two colleges in which students might be educated for the promotion of science, learning, worship, for the support and exaltation of the Christian faith, and for the improvement of the liberal arts and sciences. His preparatory college or school at Winchester was called the preparatory college or school at Winchester, and in 1328 he had before this purchased more of the grounds of the manor of the Oxfordshire college there, still called New College, to which that at Winchester was designed as a nursery, was afterwards built.

These pious and patriotic exertions however were interrupted by the political storms which overtook the church during the reign of Edward III. He had been appointed one of the council established to superintend the conduct of affairs on the petition of the parliament which met in April of that year; and in July of the same year the Duke of Gloucester and his party, with the Earl of Oxford, who, after the death of the Black Prince in June, and the rise of the parliament in July, took possession of the supplant the sick and dying king, and proceeded to overthrow all the restorations of the last. He had been in office many years before as keeper of the privy seal and lord chancellor. He was heard in his defence, before a commission of bishops, peers, and commons, of the transactions from the first to the last of the judgment was given against him upon one of the articles, involving at the utmost a mere irregularity; and upon this, under the influence of that then prevailed at court, an order was immediately issued for the sequestration of the revenues of his bishopric, and he was at the same time forbidden, in the king's name, to come within 20 miles of the court.

The next parliament, which met on the 27th of January, 1377, was wholly devoted to Lancaster; and when, soon after, on the petition of the Commons, an act of general pardon was issued by the king with the loss of the year of his jubilee, the bishop of Winchester alone was specially excepted out of its provisions. All this, in the circumstances of the time, may be taken as the best attestation to Wykeham's patriotism and integrity. He was then, as before, at the head of the Church, and his power was supreme. The disaffection of Richard II. had, however, now taken up his cause with great zeal; and, whether in consequence of their bold representations on the subject to the king, or for some other reason, it was soon deemed expedient to drop the proceedings against him, and he was allowed to remain in the possession of his lands, castles, and possessions.

But the loss of his ship out three ships of war for the defence of the kingdom and maintaining them at sea for a quarter of a year. And even from this mutiny he was released on the accession of Richard II. a few days after. But the loss of his ship out three ships of war for the defence of the kingdom and maintaining them at sea for a quarter of a year. And even from this mutiny he was released on the accession of Richard II. a few days after. But the loss of his ship out three ships of war for the defence of the kingdom and maintaining them at sea for a quarter of a year. And even from this mutiny he was released on the accession of Richard II. a few days after.

The business of teaching appears to have commenced both at Winchester and at Oxford in 1373; Pope Urban VI.'s bull of licence for founding Winchester College was granted by Urban VI. to a body of 100 men, consisting of the College at Oxford, which he called 'St. Mary College of Winchester in Oxford,' was begun in 1380, and was finished in 1393; that of the college at Winchester was begun in 1397, and was finished in 1333. The papal bull confirm the existing rights of the colleges at Oxford is dated 18th July, 1396. And as soon as his two colleges were erected, he entered upon another great work, which still remains a monument of his taste and munificence: he resolved to rebuild his cathedral in the greater part of its extent.

It fell to the lot of his descendant in the family to live to see that project brought to a close in about ten years or so. [WINCHESTER.] The bishop of Winchester was one of the fourteen persons appointed in 1386, on the petition of the parliament instigated by the Duke of Gloucester, to be a council to the king for one year, and in fact for that term to exercise all the powers of government. As soon as the parliament was dismissed, Richard made an attempt to arrest the Duke of Gloucester and his friends. A commission and statute appointing the council were declared by the judges, on the royal command, to be illegal and null, and to have involved all who had been concerned in procuring them in the guilt of treason. Upon this the Duke of Gloucester and his companions, the lords and commons, resented the innovation with great indignation, and resolutely asserted their right to the crown. Having encamped before London, they sent a deputation, of which the bishop of Winchester was a member, to the king; the deputies were graciously received, and returned with proposals for an accommodation; but in the mean time a body of forces which had been raised for the king in Wales and Cheshire, under the command of his minister, the Duke of Ireland, was encountered by the Earl of Derby and a part of the army of the confederated lords and commons at Radcliff Bridge in pursuit of the king.

This blow compelled Richard to yield to the present. But in May, 1389, another revolution in the government was effected by the king suddenly declaring himself to be of age, and removing the Duke of Gloucester and his friends from office. He departed in the triumph of the power of his faction. The bishop of Winchester, however, was not allowed to share in the spoils of victory, after the advice of the king's minister, the Duke of Ireland, was encountered by the Earl of Derby and a part of the army of the confederated lords and commons at Radcliff Bridge in pursuit of the king.

1909. Little is known about him; he is not mentioned by Houbraen; and Van Gool, who notices this omission of Houbraen, lived at too late a period to be enabled to learn any facts of his life. Wynants is supposed to have been the master of Houbraen, to whom some of his pictures have been attributed. He was fond of amusement, and idled much of his time in parties of pleasure, and his pictures are accordingly few in number. He generally painted small pictures, coloured with great transparency; the figures and cattle in them are not painted by him. Thomas D'Argenville, the elder, so much admired and venerated, envied a secret. These parts of his pictures were painted by several masters,—by Van Thulden, Ostade, Houbraen, Lingelbach, and A. Vandevelde, which gives some proofs to his wonderful knowledge in the dictionary, and some other books, 1670 is given as the date of Wynants' death, but there is a picture in the gallery of Schlesiehym by him, dated 1673: his name is also written in the painters' company's book of Haarlem for the year 1677. (D'Argenville, Fies des Peintres; Dillies, Gemalde zu Schlesheim.)

WYNHAM, SIR WILLIAM, the third baronet of that name, distinguished in the parliaments of Queen Anne and the first two Georges, was born in 1687. He was of an ancient ennobled family, and a native of Somerset. He was educated at Eton and at Christ Church, Oxford, and afterwards travelled for some time abroad. On his return he was chosen to represent his native county in parliament, and married a daughter of the Duke of Somerset. He thus entered on the public life with great advantages, which his abilities well supported. He associated himself with the Tory party, and, fascinated by the talents of Lord Bolingbroke, he joined in the pleasures as well as the privacies of that nobleman. When, however, Lord Bolingbroke in 1710, Wynham was made master of the buckhounds, and on the 18th June, 1711, was appointed secretary at war. In August, 1713, he was promoted to the chancellorship of the exchequer, and in November, there was sworn a privy councillor. In the disputes between Oxford and Bolingbroke he sided with the latter, and was entirely in his confidence. When the lord high treasurer was disgraced, Lord Bolingbroke wished to have the treasury and exchequer in the hands of the five commissioners; but this arrangement was defeated by the sudden appointment of the Duke of Shrewsbury to the vacant office. This appointment, followed by the death of the queen, put an end to the hopes of the Tory party. The Pretender to the throne had attached himself to many of the Tory ministers, and to none more to Lord Bolingbroke. Wynham himself was not free from suspicion: his intimacy with Lord Bolingbroke and his close friendship with other reputed Jacobites, caused him to be suspected of disloyalty. He was returned to the new parliament summoned by George 1, and protested in such strong language against the proclamation by which the late parliament had been dissolved, that the new parliament was only saved from imprisonment in the Tower by Sir Robert Walpole, who persuaded the House of Commons to spare him with a reprimand from the Speaker. When the rebellion in favour of the Pretender broke out in 1715, intelligence was brought to the house of commons that Sir W. Wynham was concerned in the projected rising in Somersetshire: his father-in-law the duke of Somerset offered to be responsible for him, and desired that he might not be taken into custody; but the council refused to leave him at large, and Sir William was sent to prison in his own house, contrived to escape under pretence of making preparations for his journey to London; and a proclamation was immediately issued offering 1000l. for his apprehension. For some time he eluded the vigilance of his pursuers disguised as a musician, finding that he had but little chance of escape; he surrendered himself, and was committed to the Tower. He denied all knowledge of any plot whatever in favour of the Pretender; and, whether on account of his innocence, the failure of evidence, or the influence of his connections, he was never brought to trial.

He was henceforth distinguished as one of the most active and able members of the opposition. He opposed Sir Robert Walpole on almost every occasion. The most vehement and perhaps the best speech against Walpole's Excise scheme was delivered by him in 1733. Of all the reported speeches, that in favour of the repeal of the Septennial Act in 1734 may be pronounced the most able and argumentative. In 1739, having been in the minority not voted against the address on the Spanish convents, he determined to vote with many others to secede from parliament. In expressing this resolution he applied incurring terms to the majority of the House, and was indebted, for the next time, to Sir Robert Walpole's judicious forbearance for his escape from commitment to the Tower. Nothing could have been more affecting than the scene of his release on the 1st of the 1st of the next session.

The influence of Wyndham in the House of Commons was proved by the immediate consequences of his death in 1740. He had united the Tories and a considerable portion of the Whigs in their opposition to the new ministry. The union that existed in the Ministry after his death was dissolved—the opposition was armed of half its power—and for some time the Ministry had little to dread either from the eloquence or the numbers of its opponents. He died at Wells in Somerset on the 1st of July, 1740. In the same year, his successor in the seat of Wyndham, who afterwards inherited the title of earl of Egremont from his uncle the Duke of Somerset, by a second wife, relented of William, marquis of Blandford, left issue.

Sir William was one of the most popular men of his time, and in parliament was remarkable for the force and spirit of his eloquence. The character of his oratory has been described by a great critic, Mr. Speaker Onslow: 'This was much grace and dignity in his person, and as he was the most attentive of listeners, there was no person who was more pleased with the character of his eloquence, but his eloquence, improved by use, was strong, full, and without affectation, arising chiefly from his clearness of pronunciation, and arguments; in the method of which he was by a sort of induction almost perfect, and when once his force and power in speaking that always animated had been exhibited, and his hearers had been convinced of the truth, which was indeed very ornamental, produced not only the most attentive, respectful, but even a reverent respect whatever he spoke.'

Tindal, Continuation of Rapin: Core, Memoirs of Sir R. Hillyer Correspondence, when Time: Chandler's Drop, Collins, Peerage, by Sir Egerton Brydges.)

WYNTON, ANDREW, a rhyming amateur, living during the early part of the fifteenth century, and prior of the monastery of St. Serf's Inch or Inchley, Loch Lomond, was the author of a manuscript of the history of his parentage or the periods of his birth and death. He is only known as the author of The Chronicles of Scotland, a work of considerable authority and Scottish history, during the interval between the end of the fifteenth and the beginning of the sixteenth century. It is valuable also as a specimen of the Scots language at a time when it closely resembled the English in all but the Gallicisms which pervade Chaucer and Gower, and before it had taken that distinct form which it exhibits in the hands of the poets of the latter part of the fifteenth, and of the sixteenth century. Wynton seems to have strongly felt the difficulty under which all rude chroniclers lie, of drawing a line of demarcation between the domestic and the foreign. The work is divided into nine books.

In honour of the colvyn synne
Of holy nephly, the ghylk dyeynne
Scripture lyouns, a wise cannon shinne
I would despute now this tryste
In myne lykynce and monste me
And she the nextye of the myeastyne
Salt trete fig the begynne
Of the swarte.

Accordingly the author is as good a word, and beginning at the creation, he traces through the greater part of Scripture history to the mythological period of Greece and Rome, mingling the sacred and profane strength together, and describing both the deluge of Scripture and the deluge of the nation's flood. The early and completely finished part of the Scottish annals is mixed up with these widely different

Digitized by Google
chronicles. Four books out of the nine are finished before the birth of Christ is narrated. In the printed edition of the chronicle the editor has very properly given only the hystirical titles of the chapters which do not refer to Scotland, and thus of these four books only a few fragments are printed. Wytoun is a tedious narrator, but he is spirited in his histories; and during the strange events he has to record, with the curious traditions of national superstition mingled with them, give the book considerable interest. Sir Walter Scott has been obliged to Wytoun for many striking incidents in his narrative poems. The supernatural parentage of the Sea, in the 'Lady of the Lakes,' of whom it is said,

"Of briar's birth strange tales were told, His mother watched a midnight fold," &c.

taken from the narrative of the birth of Macbeth (book iii. &c. 18). The following is an instance which will give a fair illustration of Wytoun's style. It is said of Sir David Lindsay, of Glemis, in a battle with the Highlanders in 1392—

"Sad on his horse he still standeth, Throw the body he struck a man. Wydtis his spear down to the rade: That man held but his own sword to his men, and above three, we. He present hym, moical apyre standand That man, which outwydt his spear. And with a swape share of his record: "Throw the steepy fur and the bote Three pye or fries, above the two. He struck the lymdyres to the twice: That man was no sme gore bot that last For thare he deit."

This incident is adopted by Scott, in 'The Lord of the Isles,' canto 6, thus:

"Yet still on Colunny's bindree lord, Who prays the chaste with gryme sword, His roke with sword in rest; And through his bloody tarmes beroed, And through his ellyst cirrest. Now to the earth the mountainer, Yet writhed him against the spear, And sawing his broadsword round"—

"... and the story proceedeth Grently that blon's tremendous away, The blood gushed from the wound; And the grim lord of Colunny Hath turn'd him on the ground, And taung in deathly pang, that his blade The mortal thrust so well repaid."

There are several MSS. of Wytoun's Chronicle; one in the Cottonian collection, another in the Harleian, and a third in the Advocates' Library. The best is however that in the Royal Library in the British Museum, from which Mr. David Macpherson has printed the eddication, collating it with the other. This magnificent specimen of British typography was printed in 1795, in 2 vols. 8vo. All the copies of it seem to have been printed on drawing-paper; at least the writer of this notice has never met with any copy on ordinary paper. It contains an introduction, notes, and a glossary.

X.

X to an Englishman is the representative of what might as well be denoted by the two consonants ks. But in the Greek alphabet it was merely a guttural aspirate, equivalent probably to the German ch. The cause of this change in the power of the symbol appears to admit of the following explanation:—Before the employment by the Greeks of their character Χ or x, it was their common custom to form this sound, as may be seen in Boeckh's inscriptions, rather than by ξ, of which there exist however a few examples, as in the so-called Nanian Inscription. [ALPHEIANS, p. 388, plates ii. and iii.] Now the Romans copied this Greek practice, and we consequently find in Latin inscriptions such forms as maxum, proxxymv, &c. (See the Index of Marini's Fratelli Araldi.) So again coins give us the proper name AXSIVS, where the later orthography would have been axivs; and even existing manuscripts still bear traces of this orthography. Thus the Medieval MS. of Virgil has e x s (Aen., viii. 418), XXSVT (Aen., viii. 567). But the Romans, being generally averse to the aspirated letters (h itself, though written, seems not to have been pronounced by them), had little or no occasion for the character x except in this combination with an ε. The very sight therefore of an x, even before the eye came to the s, raised in the mind the idea of a sibilant, and thus rendered the sibilant itself a superfluous letter; which, because it was superfluous, was discarded before long; and thus the single letter x would perform the office of the two consonants xs. It may be objected to this view, that in one of the oldest inscriptions, the Bacchanaelian (See the plate in the seventh volume of Drakenholt's Livy), we have the form exdeicerent, where the letter in question already has the power of our modern x. This is perhaps an erroneous idea. It would probably be more correct to look upon the character in this word as the simple guttural, thus: exdeicere rent, from which the later form exedere rent would arise. A sibilant in this word would have given the same offence to a Roman, as κτελεων would have done to a Greek ear. It should be recollected too that the old Latin preposition had the form ex, see, as in ecfari, ecfere, &c. (for thus did Cicero write these words), and that the sibilant h was added only before a vowel. An argument against the view we have taken in reference to the change of power in the symbol might be founded upon the fact that the Spaniards employ the very same symbol as a guttural. Thus the geographical names Xeres, Xalapa, Mexico, the X has little or nothing of a sibilant character.

The letter X was the last in the Roman alphabet, neither Y nor Z belonging to it, although the majority of Latin grammarians have placed it there. On these grounds however it will be admitted that the words in which those two letters occur are not really part of the Latin language, but borrowed from the Greek, as zephyrus, zona; or from some Eastern source, as gaza. Such forms as lachryma, hyena, synea, are simply errors of modern editors. The Romans themselves wrote lacruma or lacrima, hiena, or rather hiemip, and silva. But the fact that x was the final letter of the Roman alphabet is established by an anecdote in the Life of Augustus by Suetonius (c. 86), but the reader must be careful to avoid the false reading of Cassonob, who, in defiance of the manuscripts, has substituted a z for an x.

The interchanges of x with other letters are as follows:—

1. x with c, as in the double form, already mentioned, of the Latin or Greek preposition ex or oc.
2. x with s or sk. See S.
3. x with g, as in the Latin augero compared with the Greek .Lookup, and μυρομ compared with min, mix-, and mix-, Latin.
4. x with ps, as the Latin exilis compared with the Greek φυλος. In the same way we find an illustrious Roman officer writing ιξι for ιπι, and thus too προκριμε is the superlative of προ. This change is in fact only another instance of the interchange of p and e, so common between Greek and Latin. See C.
5. x perhaps with h. Thus ξως is probably in the first syllable the equivalent of the Latin hostis and haec.

See O and N. So again hosta is probably connected with the Greek formae.

6. x with z. Thus in Spanish a z is found where the Latin has an x. For example, the Latin words cruz, paz, have become in Spanish cruz, paz, whence the name of the American towns Fera Cruz and Lo Paz.

Xalle, the Turkish name of the seeds of the Priests Christ's Thorn (Paliurus aculeatus). The genus Paliurus belongs to the natural order Rhamnaeae, and has a solid spreading calyx; 5 petals; ovate 2-angled stamens; a pentagonal disk; a 3-celled ovary, with 3 spreading indescribable fruit, which expands into a membrane near the disk, and contains a 3-celled nut. The P. acauleus, Prickly Christ's Thorn, has pubescent branches; ovate, serrated, smooth, 3-nerved leaves, with 2 spines at the base; the one street, the other hooked; the flowers are not crowded in umbels. This plant is a shrub, and inhabits the coasts of the Mediterranean, and is the common form of the hedges, for which it is well adapted, on account of the thick fleshy forms which by its branches grows close together. It has greenish yellow flowers, and the peculiar form of its membranaceous fruit, which looks like a little head with a broad-brimmed hat on it; it is said by the French Porte-Chapeau. The branches are each bent into a curve, the calyx grows in Palestine, and the thorns which grows in Palestine, it has been supposed to have afforded the materials of which the crown of thorns was made which was placed on the head of Jesus Christ. Hence the common name of this plant. The seeds are used by the native doctors of Constantinople in some of diseases, but they do not appear to have very useful properties. They are also used as a dye.

Xanthic Acid was discovered by Zeise in 1832: it is prepared by gradually adding bi-sulphuret of carbon to a solution of potash acid, and is obtained by this operation xanthic acid and xanthate of potash are formed. The salt is colourless, and crystallizes in seeds of considerable brilliancy; when exposed to the air it becomes slightly yellow, and has a cooling, sharp, poisonous taste, it is very soluble in water, but does not taste from the air; it is dissolved by alcohol, and also very slightly, by ether.

When xanthate of potash is treated either with sulphur or hydrochloric acid, it produces with about five times the weight of water, it is decomposed, and xanthic acid possessing the following properties is obtained:—

It resembles an oil, but is heavier than water, and, being insoluble in it, separates from it; it is colourless, and possesses the general properties of an acid; it dissolves in water, and decomposes spontaneously when kept under water.

From the experiments of Zeise it appears that this acid consists of—

This acid precipitates several metallic salts of a yellow colour, and hence its name; it is especially the case with the salts of copper and is characteristic of that metal.

When the xanthates are heated they are decomposed, and when xanthate of potash is subjected to distillation a limpid yellow coloured fluid comes over, which Zeise has called xanthetic oil; water however dissolves a small quantity of it; its taste is sweet and sharp, but does not seem to possess the general properties of an acid; it burns with a blue flame, and the evolution of much sulphurous and carbonic acid.
XANTHIC OXIDE. [CALCULUS.]

XANTHITE. [Pendleton.]

XANTHIPPUS. [F. W. W.]

XANTHITE consists of a congeries of small rounded grains, easily separable from each other, and not larger than small grains of sand. It occurs also in foliated masses, which are very friable, and readily fall into grains, some of which are prisms about 4th of an inch in length. It yields by cleavage a doubly oblique prism. The grains are translucent and transparent, and of a greyish yellow colour. Hardness 2-801. Specific gravity 3-221. Before the blowpipe, with borax, melts into a glass, which is yellow while hot, but becomes colourless on cooling.

According to Dr. Thomson’s analysis it consists of—

It is found in a limestone-bed at Amity, Orange County, New York, United States of America.

The cercariae of Paragonimus, mostly referred to the natural order Composita, but of which Link forms a small order called Ambrosiaceae. The genus Xanthium has monoeious flowers; the male flowers have a many-leaved involucre, tubular petals, and a palescenec receptacle; the female flowers are much inferior; four last of the single leaf, which is bilocular, and embraces 2 flowers without petals.

The species are herbs.

X. strumarium, the Lesser Burdock of English botanists, is a naked plant, with the lower leaves cordate, 3-lobed, toothed, and 3-veined. It is cultivated in cultivated places in Great Britain and other parts of Europe. X. spinosum is found in the south of Europe. It has entire or 3-lobed leaves, and is covered with 3-veined, strong, and sharp spines. It is inhabited by the Carapaces of various genera, and is sometimes used as a yellow dye; hence the generic name, from Xanthis, yellow.

(Koch, Flora Germanica; Burnett, Outlines.)

XANTHO, Dr. Leach’s name for a genus of Brachyurus Curassacaeae, placed by M. Milne Edwards among his Cancriens Argus [Platyxeris], between the genera Lagenostoma and Chloridius.

Generic Character.—Carapace very wide, but never regularly oval, and with but little convexity; its surface less smooth, and not curved in its longitudinal direction, except on the anterior portion. Front ordinarly advanced, lamellar, and nearly horizontal; a narrow fissure divides it into two lobes, the border of which is more or less notched in the middle. The orbit is extended, and divided by those of the crabs and of Zostemis. The latero-anterior borders of the carapace are generally prolonged much less backward than in the preceding genera of Cancriens Argus, and only reach ordinarly to the level of the middle of the genital region, so that the posterior portion of the carapace is scarcely more extended than the posterior portion. The latero-posterior borders are nearly always long, straight, and directed much less obliquely inwards than in the preceding genera. The antennary fossae are narrow, transversal, and separated by a delicate partition. The basal joint of the external antenna is placed as in the Zostemis, but in general shorter. The external jar-feet present nothing particular. The sternal plate is inclined to the lateral jar-feet short, and terminated by a very short tarsus, armed with a single horned nail. The abdomen presents seven segments in the female, and in general five in the male.

Geographical Distribution.—The species are numerous, and found in all seas. M. Milne Edwards thus arranges them—

§ A. Species whose carapace is granulatus or tuberculatus above.

a. Four last pairs of feet equal, neither spiny nor toothed.

a*. Carapace covered with rounded and isolated granulations.

Example, Xantho biritissimus. Description.—Carapace granulatus and very strongly embossed throughout its extent. General form nearly oval. Latero-anterior borders of the carapace very much curved and divided into four obtuse lobes. Latero-posterior borders very concave. Ptyerogostomian regions granulatus and hollowed with small furrows, which are continued with the notches of the latero-anterior borders. Feet moderate and compressed. Body entirely covered with small stiff hairs. Length about seven lines.

Locality.—The Red Sea.

a**. Carapace covered with small tubercules conjoined in double rows and having a worm-eaten paper.

Example, Xantho vermiculatus. Description.—Carapace hardly convex, strongly embossed, and presenting on each embossment a great number of united tubercules in form lines which are elevated and carved as it were on each side, which unite in their turn and give the carapace a worm-eaten appearance. Latero-anterior borders divided into four lobes with triangular teeth, whose borders are dentilicated; latero-posterior borders divided into four lobes with much inclined, narrow and deep notch towards the middle of the anterior border of the third joint of the external jaw-feet. Feet with the appearance of being worm-eaten, both above and externally; first pair moderate and rounded above; claws with the tips of the feet last pair of feet with the upper border trenchant and hairy. Length about two inches. Colour whitish. (M. E.)

a a. Four last pairs of teeth neither spiny nor toothed. (Carapace tuberculatus.)

Example, Xantho Reynaudi. Description.—Carapace with very distinct and embossed regions, tuberculous throughout its whole extent, slightly convex, strongly truncate behind and covered with tubercles which do not reach into the two sinuous and truncated lobes; latero-anterior borders reaching only a little below the level of the stomachal region, and armed with four large triangular and tuberculous teeth; latero-posterior borders slightly convev and very long; anterior feet with a swollen appearance and covered internally and externally with large rounded tubercules; claws pointed; succeeding feet slender, rather long, and carrying on the upper border of their third joint a row of six or seven large teeth. Inferior surface of the body highly armed. Length about two inches and a half. Colour red mingled with yellow and white. (M. E.)

§ B. Species whose carapace is not covered either with granulations or tubercules.

b. Hands and feet last four last pairs of feet without a trenchent crest on their upper border.

b*. Carapace embossed and dotted throughout its extent (its latero-anterior borders strongly toothed).

Example, Xantho impressus. Description.—Carapace hardly convex and covered with embossments whose surface is unequal and dotted. Front slightly inclined and divided into four rounded lobes, the two middle of which are large and projecting, and the two lateral ones very small. Latero-anterior borders taking their origin much below the level of the orbit, not prolonged beyond the level of the middle of the genital region, and divided into four large rounded lobes. Anterior feet with a great bi-lobate tubercle on the inner border of the carapace; hands presenting neither tubercles nor spines; claws pointed and rounded at the end; four last pairs of feet rounded. Length two or three inches. Colour yellow, washed with red.

Locality.—The Isle of France. (M. E.)

b**. Carapace embossed anteriorly, but flat on its posterior half (its latero-anterior borders strongly toothed).

Example, Xantho levius. Description.—Upper surface of the carapace remarkably convex; lower border of the opening of the internal case of the orbit advancing to the level of the fourth joint...
the external antenna. Latero-anterior borders of the ear-

nose divided into four teeth; anterior feet moderate; hand

rounded above; upper border of the four last pairs of feet

rounded, furnished with a great number of small tubercles

and very hairy. Length about three inches. Colour

reddish yellow.

Locality.—The Isle of France. (M. E.)

b.*** Carapace without notable embossments, even

on its anterior portion.

b.***. Latero-anterior borders delicate and

deeply cut.

Example, Xantho eranthis. Description.—Carapace

much widened and smooth; front divided into two very

wide, truncated, lamellar lobes, with nearly straight edges; 

latero-anterior borders divided into three delicate and

nearly square lobes, followed by a fourth triangular tooth. 

Anterior feet very unequal and moderate; claws

slightly compressed and curved downwards and

outwards. Stinging feet nearly as in the pre-

ceding species, but more slender. Length about 10 lines.

Locality.—The coasts of Peru. (M. E.)

b.***+. Latero-anterior borders thick and entire, or

only presenting two or three tubercles, 

which hardly project at all.

Example, Xantho Gaudichaudi. Description.—Front

slightly advanced, very narrow, and deeply divided into four rounded and very projecting lobes. 

General form closely resembling Xantho fluidus. Length

about two inches.

Locality.—Chili. (M. E.)

b.***. Fore and four last pairs of feet furnished above

with a longitudinal crest.

Example, Xantho incisus. Description.—External surface of the hands furnished with many horizontal rows of small tubercles. Carapace

very wide, slightly convex, strongly embossed, and pre-

senting on the stomach and hepatic regions many small

transverse crests. Front scarcely inclined, and divided

into four rounded lobes, the two external of which are very

small. Latero-anterior borders of the carapace divided

into four teeth, the two first of which are rounded and

compressed, and the two last triangular and carinated above. 

Anterior feet granulous. Length about an inch. 

Some hairs on the carapace and on the feet.

 Locality.—Australasia.

We illustrate the genus by Xantho fluidus, which is common 

on the English and French coasts, about two inches in 

length, of a reddish brown colour, with black claws.

East Indian plants have been described under Xantho-

chymus by Dr. Roxburgh. Of these the X. pictus is 

the most important. This plant is the X. pictus of 

Linnaeus. It has lanceolate acuminate leaves, yellow petioles, 

and fruit 1-4-seeded. It is a native of the East 

Indies, in valleys among the Ceylon Mountains. It has 

a large tree with white flowers and a yellow fruit resembling 

the orange. The fruit is eaten by the natives, and is 

inviting to the eye, though the flavour is not pleasant to a 

European taste. When nearly ripe the fruit is filled by 

a resinous juice, of the consistency of cream, and of 

a yellow colour, and having acid properties similar to 

those of gamboge, which is imperfectly soluble in petroleum 

less so in water, but in alkaline solutions more. It makes 

a pretty good water-colour, either alone for yellow, or 

with blues to form a green. There is little doubt but that one 

of the vegetable secretions known in the market as gano 

boge is the produce of this plant. The genus 

at present given by Garenin is in the form of rolls; that from Xantho-

chymus is in small granular brittle pieces, and is used

both as a colour and as a purgative.

(Don's Miller; Lindley, Nat. Syst.)

XANTHOMYZA. [XANTHOMYZA.]

XANTHOMYZA, the correct form of XANTHOMYZA, 

which last is used by Mr. Swainson and the catalogues 

generally.

XANTHOPHYLL. It is well known that in among 

the foliage of many forest-trees becomes of a deep 

yellow colour, which, according to Berlerius, is on the 

replacement of the green colouring -matter of the 

leaves, or Xanthophyll, by a peculiar yellow colour 

matter which he calls Xanthophae. The plant 

which this are, that it is a fatty substance of a deep yellow colour, which melts between 100° and 120° Fahr.; it is insoluble in water, but dissolves copiously in alcohol and ether; is a solution exposed to air and light, blackened, and alkalis dissolve it sparingly; the solution, which is of 

a yellow colour, is also destroyed by the action of light.

XANTHOPROTEIN ACID. According to Maier, this 

acid is formed when albumen or any other protein con- 

tained is boiled in nitric acid. It is composed of the free 

escape of azotic gas, and yield a yellow-coloured solution 

while oxalic acid and ammonia are formed.

Two equivalents of protein, 1 of water, and 2 of the 

acid yield 3 of oxalic acid, 2 of ammonia, and 1 of the 

proteic acid. After being washed away with boiling water, 

the acid exists as a tasteless yellow-orange powder, 

which combines with acids as perfectly as with bases; its 

combinations with the latter dissolve in water, and give 

dark and coloured solutions. This acid consists of carbon, hydrogen, 

oxygen, and azotic, combined with water.

XANTHORHIZA, a genus of plants belonging to 

the natural order Ranunculaceae and the tribe Primens. It 

has a calyx composed of 5 deciduous sepals; 5 petals 

2 to 3-seeded carpels, but the seeds are usually 

aborted from abortion. There is last species of this genus 

Xanthorphiza apifolia, which is a small shrub, with irregularly pinnate leaves, with 5 to 7 leaflets, which are deeply serrated. The flowers are small and dark purple, and arranged in branched racemes, which are numerous and arise with the leaves from the scaly buds. The roots are creeping, and of a yellow colour, hence the generic 

name. It is a native of North America from Virginia to 

Georgia, where it grows on the shady banks of rivers. It 

is commonly known by the name "wild lily of the valley." The root 

of the plant is intensely bitter, and is used in America 

as a tonic, but the plant has also acid properties.

The yellow-root will grow in any common garden soil, 

and is easily propagated by means of the suckers, which 

should only be cut from the roots, and so if they 

is good and valuable abundance.

XANTHORNUS, the generic name used by Briceau 

and Cuvier for certain Orioles. The generic character is given 

in the article SUNNINUS, p. 174.

The Baltimore Oriole, or Golden Robin, will serve as 

an illustration of the genus.

Description.—Tail nearly even. Male, orange; head 

neck, back, wings, and tail black; the lateral tailfeathers 

orange at the summit. Length seven inches. 

Female and Variegated, with the back grey and 

mottled with yellow, and the tail orange.

Locality, Habits, &c.—These brilliant birds arrive in 

the United States from South America very early in May. 

The males comefirst. Their natural notes are mellauer.

Digitized by Google
they whistle loud and clear; but they are great mimics, and catch up the note of any bird that comes nigh them. Their food consists principally of small caterpillars, beetles, ants, and other insects, but neither young peas nor fruit come amiss to them.

There is nothing,' says Nuttall, 'more remarkable in the whole instinct of our Golden Robin than the ingenuity displayed in the fabrication of its nest, which is, in fact, a tedious cylindrical pouch of five to seven inches in depth, usually suspended from near the extremities of the high trooping branches of trees (such as the elm, the pear, or apple-tree), wild-cherry, weeping-willow, tulip-tree, or buton-wood). It is begun by firmly fastening natural strings of the flax of the silk-weed (Aceldras), or swamp-hollyhock (Hibiscus paaltris), or stout artificial threads, round two or more forked twigs, corresponding to the intended width and depth of the nest. With the same materials, willow, or any accidental raellings, strings, thread, sewing-silk, tow, or wool, that may be lying near the neighbouring houses, or round the grafts of trees, they interweave and fabricate a sort of coarse cloth into the form intended; towards the bottom of which they place the real nest, made chiefly of lint, wiry grass, horse and cow hair, sometimes in deft of hair, lining the interior with a mixture of slender strips of smooth vine-bark, and rarely with a few feathers, the whole being of a considerable thickness, and more or less attached to the exviation. Over the top, the leaves as they grow out form a verdant and agreeable canopy, defending the young from the sun and rain. There is sometimes a considerable difference in the manufacture of these nests, as well as in the materials which enter into their composition. Both sexes seem to be equally adept at this sort of labour, and I have seen the female alone perform the whole without any assistance, and the male also complete this laborious task nearly without the aid of his consort, who however in general is the principal worker. I have observed a nest made almost wholly of tow, which was laid out for the convenience of a male bird, who with this aid completed his labour in a very short time, and frequently sung in a very ludicrous manner with his mouth loaded with a large mass of tow. So eager are they to obtain fibrous materials, that they will readily tug at and even untie hard knots made of tow. In Audubon's magnificent plates, a nest as represented as formed outwardly of the long moss (Tillandia) would be superfluous in the warm forests of the lower Mississippi. A female, which I observed attentively, carried off to her nest a piece of lamp-wick 10 or 12 feet long. This long string and many other shorter ones were left hanging out for about a week before both the ends were wattled into the sides of the nest. Some other little birds, making use of similar materials, at times twitched these flowing ends, and generally brought out the busy Baltimore from her nest in great anger.' (Manual of the Ornithology of the United States and of Canada.)

The four or five white eggs are faintly tinged with bluish, and marked, chiefly at the larger end, though sometimes scatteringly, with straggling serpentine dark brown lines and spots, and fainter hair-streaks, looking sometimes almost like real hair, and occasionally lined only and without spots, according to Nuttall, who says that the eggs which he had seen did not resemble Wilson's figure; though they may vary much. Period of incubation fourteen days, according to Audubon, who states that in Louisiana, where they arrive early in the spring, they frequently rear two broods in the season.

XANTHOXYLACE.E, a natural order of plants belonging to Lindley's Gynoecie group of polypetalous Exocots. It possesses the following essential characters — The flowers are unisexual and regular: the calyx in three, four, or five divisions; the petals usually of the same number as the divisions of the calyx, usually longer than the calyx, and sometimes absent; the stamens are generally twisted and convolute: the stamens are equal in number to the petals, or twice the number, and arise from around the base of the stalk of the abortive carpels; in the female flowers they are either absent or very imperfect; the ovary is made up of the same number of carpels as there are petals, or of a smaller number; the seeds are either distinct or more or less combined; there are mostly two ovules in each cell, sometimes four; the styles are more or less combined, according to the cohesion of the carpels;
endocarp, the seeds are solitary or twin, pendulous, usually smooth and shining with a testaceous integument; the embryo lies in the midst of a fleshy albumen, the radicle is superior, and the cotyledons ovate or flat. The species of plants belonging to this order are trees or shrubs, with exstipulate, alternate, or opposite, simple or bipinnate leaves furnished with stellate hairs. The flowers are either axillary or terminal, and coloured grey, green, or pink.

The plants in this order were included originally by Jussieu in his Terebinthaceae. They were first separated by Martius, and subsequently by Adansoni, for the latter Xanthoxylum, which was subsequently adopted by Adrien de Jussieu. On the affinities of this difficult order Adrien de Jussieu has the following remarks:—"The place originally assigned, and for a long time preserved, for most of the genera of Xanthoxylaceae is sufficiently near affinity between the seeds and the need to be called Terebinthaceae. If, with Brown and Kuth, the latter are divided into several orders, Xanthoxylaceae will be most immediately allied to Burseraceae and Connaraceae, agreeing with the former in the genera with simple fruit, and with the latter in having a compound one. Notwithstanding the distance which usually intervenes in classifications between Auranthaceae and Terebinthaceae, there are nevertheless many points of resemblance between them; Correa de Serra points out a likeness between the Xanthoxylaceae and the other through Cookia. Kuth, in new-modelling the genus Amyris, and in considering it the type of a distinct order, suspects its near affinity with Auranthaceae. We cannot therefore be surprised at the strong affinities existing between the families of Xanthoxylaceae and Terebinthaceae. A mixture of bitter and aromatic principles, the presence of receptacles of oil, that are scattered over every part, which gives a peculiar dotted appearance to the leaves, and which cover the rind of the fruit; all these characters give the two families a considerable degree of analogy. This has already been indicated by Jussieu in speaking of Todalia, and in his remarks upon the families of Auranthaceae and Terebinthaceae; and it is confirmed by the continual mixture of the two in the herbaria of the native and the introduced genus Terebinthaceae, Xanthoxylaceae, and Auranthaceae. The fruit of the Auranthaceae is however extremely different; their seeds resemble, as they do, Terebinthaceae, and are on that very account at variance with Xanthoxylaceae, but at the same time establish a further point of affinity between them and some Rutaceous plants which are destitute of albumen. Unisexual flowers, fruit separating into distinct cocci, seeds solitary, or twin in these cocci, enclosing a usually smooth and blackish integument, which sometimes has a fleshy albumen surrounding an embryo, the radicle of which is superior,—are all points of analogy between Xanthoxylaceae and Euphorbiaceae, particularly between those which have in their male flowers four ovule-bearing stamens inserted around the rudimentary rudimentary stigmas, a pistil, and in the female flowers cells with two suspended, usually collateral ovules. Finally several Xanthoxylaceae plants have in their habit, and especially in their foliage, a marked resemblance to the Ash. The discordant flowers of Fraxinus, its ovary, the two cells of which are compressed, having a single style, two ovules in the inside and scales on the outside, and which finally changes into a samara, which is 1-seeded and 1-seeded by abortion,—all establish certain points of contact between Ptelea and Fraxinus! (Lindley, Nat. Syst., p. 140.)

The species of Xanthoxylaceae are found chiefly in America, especially in the tropical parts. A few of the species are found in Africa, in the Isles of France and Madagascar, in India and China. One only is a native of New Zealand.

All this order to a greater or less extent possess aromatic and pungent properties. The species which are best known and used on account of these properties belong to the genera Xanthoxylum, Ptelea, Ptelea, Ptelea, and Auranthaceae. The following are the essential characters of these genera:—

**Xanthoxylum.** Calyx 3-4-5-parted, with an equal number of petals and stamens; the styles equal in number to the carpels, distinct or connected at the apex; the carpels 1-5, sessile or stipitate, 2-valved, 1-2-seeded; the leaves simple, ternate, and unequally pinnate.

**Ptelea.** The calyx 4-5-parted; the petals 4-5, the stamens 4-5, the flower compressed, 2-3-seeded; the cells 1-seeded, tergid in the centre, each cell expanded into an orbicular reticulated wing; the leaves mostly of the same or sometimes of five leaflets.

**Todalia.** The calyx 5-toothed; the petals 5, the stamens 5, the stigma almost sessile, petals; the fruit fleshy, 5-furrowed, 5-seeded; the seeds 1-seeded; the trinodulate; the male and female flowers on different branches.

**Auranthaceae.** The flowers polygamous, the calyx 5-leaved, the petals 5; the stamens 10, unequal; the style 3, rising from the notches of the ovaries; the carpels 5, tongue-shaped, compressed, membranous, tunic in the middle, 1-celled, 1-seeded; the seeds compressed, albumen absent; the ovules 6-7; the seeds numerous, smooth; the flowers and fruits borne in racemes, 1-2-ranked, paniculate, or paniculate, or on axillary spurs.

The species of Xanthoxylaceae are trees, or shrubs with the petioles, leaves, and branches usually furnished with prickles. Like the whole order to which they belong, they possess aromatic and pungent properties, and are in the countries where they grow under the name of Peppers.

**X. fraxinimum** has unequally pinnate leaves with 3 or 5 pairs of oblong oblong—ovate sessil fruits, thick scented petioles, stipular prickles, and axillary inflorescences. This plant is a tree attaining a height of fourteen or fifteen feet, and is an inhabitant of North America from Canada to Virginia. The bark of this tree and its capsular fruit have a hot acid taste, and are much used as a remedy in the treatment of the toothache. It is of the latter use that this name is applied, and this name is also applied to all the species of Xanthoxylum. A tincture of the bark is recommended as a remedy in rheumatism.

**Ptelea** is a native of Brazil, in the province of Sao Paulo, in the Province of Brazil. It has white flowers, unequally pinnate leaves, with 3 or 6 pairs of oblong, blunt, crenate-serrate, nearly sessile leaflets, which are glandular on the margins; the rachis hardy winged; the flowers in racemose panicles. This tree is called *Ptelea tomentosa* by Linnaeus, and the name is now applied to all the species of Xanthoxylum. A tincture of the bark is recommended as a remedy in rheumatism.

**X. fraxinenum** is a native of the East Indies, in the Province of Badunga. It is armed with small incurved prickles, and has unequally or abruptly pinnate leaves, with 5 or 6 pairs of unequal ovato-lanceolate, entire, acuminate, smooth leaflets. It is called in India *Badrunga*, and the natives use the seeds, which have a warm spicy flavour, medicinally.

The fruit is about the size of a pea, and the outer coat contains an exceedingly pungent piquant and pungent juice, which is supposed to have a piquant and pungent juice, which is supposed to be the origin of the fine scent which Columbus perceived before discovering the island of Cuba.

Most of the other species of Xanthoxylum possess aromatic properties, and are used for condiments or medicines. The roots, and seeds, and seeds of *X. kotschyi* called *трибул*, by the natives, are used in India for intoxicating fish, and are supposed to be the *Fugu hrak* of Annam. In Japan the capsules of *X. piperitum* are used as a substitute for pepper. A number of the species are also held to be antidotes to the action of poisons on the system, and there can be little doubt that the secretions of these plants would be found very stimulant remedies in many diseases. The hard species will grow in the open air in this country, and are well
adapted for ornamenting small shrubbery. They may be propagated by cuttings, or by slips of the roots, which should be planted in pots and placed in a hot-bed until the young plants are strong enough to be removed.

The species of *Bucea* possessing medicinal properties are the *B. antisynderteria* and *B. Sumatrae*. The former is a native of Abyssinia, and is known by its quite entire leaves, which are clothed with small villi on the nerves beneath. This plant is known in Abyssinia by the name of *Wood-goose*. It is used in that country as a specific in dysentery. It contains in its bark an active principle, which resembles Strychnia in its effects, but is from 12 to 16 times less energetic than that alkaloid. The *B. Sumatrae* is a native of Sumatra, the Moluccas, and China, and is said to have properties very similar to those of the first species.

*Welcker, an* (1839), of Mauritius, *Xanthus*, *Xanthus indica* is adapted to the Archipelago. *XAN'THUS* is a more or less resinous, aromatic, and is employed in India as a remedy against the remittent fevers which are caught in the jungles of the Indian hills.

The species of *Todalia* are dwarf shrubs, with alternate trifoliate leaves, full of pellucid dots. The *T. ter-leata* is covered with recurved prickles, and has ovate-oblong leaves. Various species of this species have been recorded, and are found in various parts of the East Indies, in Ceylon, the Mauritis, Malabar, and the Indian Archipelago. It is hardy, and aromatic, and is employed in India as a remedy against the remittent fevers which are caught in the jungles of the Indian hills.

The species of *Althana* are large trees, and their timber is used for various purposes in the countries in which they grow. *A. glandulosa* is a native of China and the Moluccas, where it is called *Althana*. It attains a height of 30 feet, and has unequally pinnate leaves, with the leaflets glandular beneath the teeth. The leaves of this tree are three feet long; the flowers are of a whitish green colour, and have a disagreeable odour. When the bark is wounded it gives a resinaeous juice, which hardens in a few days. The wood is heavy and hard, and is susceptible of a very fine polish. This tree grows well in England, and is a handsome addition to ornamental plantations. It is easily propagated by slips of the roots.

*Malabarica* is a large tree, and is a native of Malabar. It has a large fruit and very large leaflets. The root is bitter. The *A. amara* is a native of India. The wood is used for making sheaths for spears, &c. A resinous juice flows from the bark when wounded. The fruit is triturated with maize and mixed with rice in decoction.

*XANTHUS* [LYCIA].

XANTHUS [XANTHOCLEAE].

XANTHUS [LYCIA].

XANTHUS, [XANTHOCLEAE], one of the early Greek historians, as, according to Suidas, a son of Candaules, and born at Sardes. Strabo (xiii., p. 628) admits, with other writers, that Xanthus was a Lydian, but he says it is not known by what name he was called. He is said to have written the history of Lydia, which he lived, we know, from a fragment of Phorus, that he was older than Herodotus, who is even said to have been induced by Xanthus to undertake his great historical work. But it appears that Xanthus cannot have written the whole of the history of Lydia, for the notion of the Persians taking of Sardes (the Ionians, in n.c. 499),—agrees with these facts. Xanthus wrote a work on Lydia (Achaeus), in four books, in the Ionic dialect, of which however only a few fragments are extant. It was written at Sardes, and was composed of the notices of Xanthus, who wrote about the time of the taking of Sardes (by the Ionians, in n.c. 499),—agrees with these facts. Xanthus wrote a work on Lydia (Achaeus), in four books, in the Ionic dialect, of which however only a few fragments are extant. It was written at Sardes, and was composed of the notices of Xanthus, who wrote about the time of the taking of Sardes. Also, as Xanthus himself states, on the authority of the Persian historian, Xanthus, who wrote about the time of the taking of Sardes, and was composed of the notices of Xanthus, who wrote about the time of the taking of Sardes, it is also known that Xanthus was also a native of Cappadocia, that Dionysius surnamed Scythe-
to make us regret the loss of his works. An anecdote in Laerlius is pertinent, as showing that he did not expect a person to come to the study of philosophy without the necessary preparation. A man who was unequipped with mathematics, geometry, and astronomy wished to become his pupil, but Xenocrates told him to be gone, for he had not yet got hold of the handles of philosophy.

(Diogenes Laerlius, iv., Xenoareus, and the Note of M. de Beaucourt, *Greeks and their Doxopolc Studies*, vol. ii.)

XENO CRATES (Xenokrates), of Aphrodias, a Greek physician, who is commonly supposed to have lived in the reign of the emperor Tiberius (A.D. 14-37), though some critics are inclined to place him about B.C. 40, but on the other hand this point is a topic for discussion. Respecting the life and literary activity of Xenocrates we know nothing, except that he wrote a work 'On the Advantages or the Nutriment derived from Animals' (μαθηματική ἐπιστήμη τῶν θηρίων), a work which was never not quite complete, was first published by Con. Gesner, with a Latin translation by J. B. Bovaruius, and Scholia, Zürich, 1593, 8vo. More complete MSS exist at Hamburg, in the Vatican library, and at Paris, and from them the editors have completed the text, and given us the treatise. The new edition after that of Gesner is that of J. A. Fabricius, in his 'Bibliotheca Graeca' (ix., p. 433, &c. of the old edition), which was followed by that of J. G. F. Franz (Frankfort and Leipzig, 1779, 8vo., with various readings and notes, and a glossary; a second improved edition appeared at Leipzig, 1779, 8vo.), and that of Naples (1794, 8vo., with new various readings and notes by the editor Caietanus de Ancora). The best critical edition of the Greek text is that of A. Coray (Paris, 1814, 8vo.), in which Coray contains the work on the saltation of things. It is Coray's opinion that the author of the work 'On the Nutriment derived from Animals' is not the physician Xenocrates, but the philosopher Xenocrates.

XENOPHON (Xenophon), a native of Colophon in Ionia. His period is uncertain. Diogenes says that he flourished in the 60th Olympiad (B.C. 538), which will bring him somewhat about the period of Anaximander. Cicero says that he lived a little before Anaximander, fixes his birth in the 40th Olympiad, or about B.C. 620. Though it is not said that he ever resided at Elea (Velia) in Italy, yet this must be assumed to be so, as he is always considered the father of the Eleatic school. Elea was founded by the Phocaeans of Ionia, after they had left their country, which was invaded by the Persians under Cyrus (B.C. 546). The date of the foundation of Elea is fixed about B.C. 536; but there is no direct evidence to the fact that Xenophanes was one of the colonists of Elea. The statement which Diogenes makes is, that, being a native of his country, he lived at Zancle and Catania in Sicily, which is rather vague. According to Timaeus, Xenophanes was still living in the time of the first Hiero and Epiphanes, about B.C. 477, which is entirely inconsistent with the statement of Aristotle. His verse, however, by Diogenes Laerlius make him ninety-two years of age at the time when they were written, and, according to the chronology of Apolloeus, this would be his age in the year 424, but according to Aristotle he lived till the time of Darius and Cyrus; and the first year of the first Darius is B.C. 521. In all this uncertainty perhaps it is safest to adopt the opinion that he lived between the time of Pythagoras and Heraclitus, for he mentions Pythago-

rastas and the doctrines attributed to him.

Xenophanes was a poet and a philosopher. He was one of the eminent poets of Greece, and his elegies are of the symposiac character. A pleasing fragment of one of his symposiac poems is preserved in Athenaeus (παρ. 482 ed. Cassaub.), who has also preserved some of his epigrams (x. p. 418), in which he expresses words of the audacity of likening the divine to the human is added, that if animals could make representations of the deities, they would make the representations like themselves. Assuming that the deity is the most perfect being, and that, however unlike, all endowed with equal powers of seeing, comprehending, and hearing; he is the comprehensive unity of all things, which all things are, or, as Cicero expresses it, 'he is the last of men, but the first of gods,' and for God, unproductive and eternal. He is eternal, because he could not proceed from anything else; pure intellect, or reason. His notions of the deity were obscurely express'd, and not very logically maintained in his assertion that the deity is neither moving nor at rest. God rules and directs all things as they appear to us in the imperfect manifestation of the one eternal. We cannot through them attain to a perfect knowledge of what he is, and all our speculations on the true nature of things are vain.

"No man has seen the truth, and man shall never know what is that truth of God and the Universe."

'To those who shall choose to say what's near to truth, Man is set over all the universe, and is a confused world, and he's a noble soul, and he's a noble soul in all his knowledge.

Thus God's true nature cannot be known. Men contemplate individual things as they appear, which is no true existence of themselves, and while they seek to reach the knowledge of God, he is distracted by various and the appearances to which he cannot apply his mind. Something that he seems to be beyond his own nature, and he does not desire to know his own nature. His doctrines, the striking feature of which is the reflection of the opposition between the pure truth and the various appearances. [ELEATIC SCHOOL.] His philosophy, however, is not well understood, and it is difficult to reconstruct this part of his system, as it is not easy to see from the extant fragments what connexion between his physical and theological views is not true of his physical system, as it is not true of his philosophical system. Apollodorus is not worth mentioning, and as an isolated fact, that, since he was a native of Colophon, he said that the moon is inhabited, it is not true that it contained many cities and mountains. The remarks that his verses were not so good as those of Ulysses.

XE-NO-PHON ('Xenophon'), the son of Gryllus, an Athenian citizen, was a native of the Attic deme Ereucha. The only extant biography of Xenophon is by Diogenes Laërtius, which, as usual, is carelessly written; but this biography is scattered notes of antient writers, most of which can be considered Xenophon's own works, are the only materials for his life.

There is no direct authority either for the time of Xenophon's birth or death, but these dates may be approximately determined from the books of Thucydides and the writings of Xenophon himself. It is generally agreed that Socrates saved Xenophon's life at the battle of Delium, a.c. 424, a fact which there seems no reason for rejecting, and from which it may be inferred that Xenophon was born about a.c. 444. In his 'Helleonici' (vi. 4, 35) he says, "Xenophon, the youngest of the pupils of a huge rambler, which took place a.c. 397, and Xenophon was of course alive in that year. This agrees well enough with Lucian's statement that Xenophon attained the age of above ninety ('Macrob., ii. 24)."

Such has been said as to Xenophon's age; but he did not reduce to any systematic form the mode in which the Deity must be viewed in relation to the visible phenomena. He speaks of the Deity as a self-existing all-powerful Being; and he also speaks of all things as being God. Thus his system, so far as we can ascertain, left room either for the Pantheistic interpretation or for the doctrine of pure Deism. Aristotle says (Metaph., i. 5) that Xenophon introduced the doctrine of the unity of the one according to reason and the one according to nature, but neither did he ascertain the nature of each, but looking at the whole heavens he said, The one is God. The system of Xenophon is discussed at great length by Cousin (Bisog, Univ., art. 'Xenophon'), and with considerable ingenuity. The following paragraphs in the present article will indicate all the sources which the reader may wish to consult on this obscure subject.

The work attributed to Aristotle, entitled 'On Xenophon, Zeno, and Gorgias,' should be entitled 'On Mellissus, Xenophon, and Gorgias.' It is one of a rare work, which, as far as I am able to judge, attempts a view and a criticism of the ELEATIC philosophy. (Biographical Dictionary of the Society for the Diffusion of Useful Knowledge, art. 'Aristotle.')

The chief fragments of Xenophons are collected in the great works of Diogenes Laërtius and of Diogenes Phœnix, which are sometimes called Xenophanes.

The capture of Thebes (Socrates) took place a.c. 398, and Xenophon himself was then in Thebes. He was wounded and fell into the hands of the Persians. He was conducted to Susa, that he went before a.c. 397 than after. It is not known if Xenophon wrote anything before the year a.c. 401, though Lebronne with considerable plausibility would assign the composition of the 'Banquet,' or 'Symposium, and of the 'Hiero,' to a period before a.c. 401.

There is another question in the life of Xenophon that remains to be discussed, which is somewhat connected with the chronology of his own life and with that of Thucydides. Laërtius states, 'It is said that Xenophon made the books of Thucydides which he had not written himself known, though it was in his power to appropriate them to himself.' There has been a difference of opinion as to the time of the death of Thucydides, and Dodwell, by misreading the passage in Thucydides (iii. 116) as to the third eruption of Aetna, which is the one mentioned, has concluded that he was alive in the year a.c. 395. But this is a mistake. The third eruption there spoken of is that of the year b.c. 423, the sixth year of the Peloponnesian war, and there is no evidence to render it in the slightest degree probable that he ever finished it. That he intended to finish it, is clear enough from the first chapter of the eighth book. Xenophon commence where the history of Thucydides breaks off, and are a continuation of the work of Thucy- dides. Thucydides was recalled from exile b.c. 403, but it is not known how long he survived his recall. The fact that he was not having finished his history leads to a probable conclusion that he did not survive the termination of the war many years, but such conclusion is only a moderate probability, for there are many reasons besides want of time, why a man does not finish a large undertaking.

Lebronne assumes that Thucydides died at the year a.c. 402, but there is no evidence for fixing on this year, and Lebronne has been induced to do it simply in order to give to Xenophon the honour of making known the events of the war before the year a.c. 401. There are no certain, he says, that Xenophon was at Athens in the year a.c. 402. But though we may admit the truth of the story, that Xenophon was the first editor of Thucydides, and may even have added the eighth book from the materials collected by Thucydides, there is no reason for fixing the date of this publication before the year a.c. 401 rather than after.

In a.c. 410 Xenophon went to Sardes to Cyrus, the Persian, the brother of Artaxerxes Memon, king of Persia. He is said to have advised Cyrus to go to Delphi and ask the god (Apollo) to what gods he should sacrifice and make his vows in order to secure success in the enterprise which he meditated. The god gave him his answer, but Xenophon blamed him for not asking whether he should undertake the voyage or not. However, he had obtained an answer from the god. Xenophon advised him to follow the god's commands, and accordingly Xenophon set out for Sardes, where he found Cyrus and Xenophon just ready to leave the city on an expedition. This story is characteristic both of Socrates and Xenophon.

It was given out by Cyrus that his expedition was against the Persians, and all the Greeks in the army were deceived, except Clearchus, who was in the secret. The object of Cyrus was to detach his brother, and to send an army to hold a short time the city of Ephesus. The two brothers met at Cumae, and not far from Cumae, Cyrus fell in the almost bloodless battle that ensued. His barbarian troops were discouraged and dispersed, and the Greeks were left alone in the centre of the Persian empire. Clearchus was by common consent mixed to take...
command, but he and many of the Greek commanders were shortly after massacred by the treachery of Tissaphernes, the Persian satrap, who was acting for the king. It was now that Xenophon came forward. He had hitherto merely followed the army of Cyrus, and had neither held a command nor even been considered as a soldier. He introduced himself to our notice at the beginning of the third book of the 'Anabasis' in that simple manner which characterizes the best writers of antiquity. From this time Xenophon became one of the most active leaders, and under his judicious guidance the rest of the troops effected a retreat across the high lands of Armenia and arrived at Traspeza (Trebisond), a Greek colony on the south-east coast of the Black Sea. [Anab.] From Traspeza Xenophon conducted the Greeks to Chrysopolis, opposite Cyzicus. Both he and the Athenian generals joined Xenophon to join him. At the request of his soldiers Xenophon conducted the troops back into Asia, and they joined the army of Thimbron (b.c. 399). Immediately before giving up the troops, Xenophon with a part of the Thimb'ron's forces returned to the plain of the Caicus, for the purpose of plundering a wealthy Persian named Asiades. The Persian was taken, with his women, children, horses, and all that he had, Xenophon received a good share of the plunder. (Anab., viii. 43.)

It is uncertain what Xenophon did after giving up the troops to Thimbron. He remarks (Anab., vii. 7, 57), just before he speaks of leading the troops back into Asia, that he had not yet been banished; but as it is stated by various authorities that he was banished for his part in the expedition of Cyrus against the Persian king, who was then on friendly terms with the Athenians, it is most probable that the sentence of banishment was passed against him in the year b.c. 399, in which Socrates was executed. It seems reasonable, therefore, that the execution of Socrates should be followed or accompanied by the banishment of his pupil, who was adding to his former offence that of putting troops in the hands of the Lacedaemonians to act against the Persian king. Letronnais, however, would place the execution of Socrates in b.c. 402, but it is much more likely that he stayed with Thimbron, and with Dereyllidas, the successor of Thimbron; and there are various passages in the 'Hellespont' which support the conjecture that the sentence was repealed after the death of Athens. Stesicleides, quoted by Diogenes, places the death of Xenophon in b.c. 359; but there is much uncertainty on this matter. (Clinton, Fast. Hell., ii. 32 and his remarks on the death of Alexander of Phera.)

Probably he died a few years after b.c. 359.

The extant works of Xenophon may be distributed into four classes:—Historical—the 'Anabasis,' the 'Hellenic,' and the 'Cyropaedia,' which however is not strictly historical, and the 'Life of Agesilaus';—Philosophical—the 'Hippocrates,' 'On Heraclea,' 'On the Return of Oracles,' 'Political,'—'Republic of Sparta and Athens,' and the 'Receives Attica,'—Philosophical!—'The Memorabilia of Socrates,' 'Economic,' 'The Symposium, or Banquet,' the 'Hetaerae,' and the 'Apology of Socrates.' Diogenes quotes many letters attributed to Xenophon, but, like many other productions of the same class, they are not genuine. The works of Xenophon as enumerated by Diogenes are exactly with those which are extant, and we may therefore conclude that we have at least as many works of Xenophon published, though all of them may not be genuine. It is true that Diogenes says that Xenophon wrote about forty books ('biblia'), but he says that they were variously divided, from which expression it is evident that he intended to reckon the several divisions or books as we ree them, of the 'Anabasis,' 'Hellenic,' 'Cyropaedia,' 'Memorabilia,' as distinct biblia, and we have left to the whole the number of thirty-eight, which is near enough to forty.

The editions of the collected works of Xenophon and of the separate works are very numerous. The 'Hellenic' was the first work that appeared. It was printed in 1503, folio, under the title of 'Republics,' and as a supplement to his edition of Thucydides, which was printed in 1502. The first edition of the works of Xenophon was printed by P. Giunta, Florence, 1503; but the 'Apology' and the 'Cyropaedia' were the only works from which he was able to give a complete text on the constitution of Athens are wanting. The edition of Andria of Asotn, 1523, folio, contains everything except the 'Apology.' The first complete edition of the works of Xenophon was the Giunta edition of 1543, 3 vol. 8vo, with a preface by Melantheum, who also added the
Apology, which had been edited by John Reuchlin (Capitoli), at Hagenau, 1530, 4to. The Basel edition of 1545, fol. printed by Nic. Brylinger, is the first which contains the Greek text with the Latin version. The editions of Henry Stephens, 1671, 8to, contain an amended text; the edition of 1685 has no Latin version, but that of 1681 has. The editions of Stephens were the foundation of three editions of Johann Loewenclau, 1772, commonly called Leucclavii, Basle, 1669, Frankfurt, 1720, accompanied by notes of W. Wessow, Leipzig, 1798-1804, 6 vols. 8vo, did nothing towards a new revision of the text, though it is corrected in many places. The most prizing edition of all the works of Xenophon is that of his own countryman Letronne. This edition is entitled 'Œuvres complètes de Xenophon traduites en Français, accompagnées du texte, de la version Latine, et de notes critiques,' 6 vols. 4to., 1797-1804. There is a seventh edition, 1824, of which (1828) contains the various readings of three MSS.; a second (1814) contains the notices of the MSS., and observations, literary and critical; and the third an Atlas of maps and plans. Gail has kept to the old text, and has made no use of his own discoveries. In the second edition of The Cyropædia, the passages of the key to which he had added a note, are not here printed. The translation of the 'Hellenica,' 'Cyropaedia,' 'Apologeticus,' and 'Anabasis,' is by Diodorus of Sicily, with the additions of a disabled archer, with some few alterations, made, as he says, for he following reason—'I was induced to copy these three versions; but the publisher of one of these versions is then that of this book contains the original of his own (de a”), to avoid all discussion, I made some alterations. There are indexes of the contents of each volume, except the first, which has only a title of the chapters, and is very insufficient,' &c. This is very moderate praise, and it is clear from the fact that in the fifth book alone of the 'Cyropaedia' the diction of Diodorus is so poor that a fresh edition deserves. Letronne published an edition of the various works of Xenophon, except the Hellenica, between 1778 and 1785, in 6 vols. 8vo. Schneider revised this edition: he published in 1818, the 'Hellenica' in 1791; the 'Memorabilia' in 1798; the 'Cyropædia' in 1801; the 'Theophrasti' in 1803; the 'Anabasis' in 1806; and the Political minor works in 1815.

The 'Anabasis,' in seven books, is the work by which Xenophon is best known. It contains the history only of the more properly of two warlike expeditions: the taxervs Memnon, and the retreat of the Greeks who accompanied him. The first book contains the march of four thousand years, from the time when the history of Thucydides ends, B.C. 411, to the battle of Mantinea, B.C. 362. The hypothesis that this history contains some historical truth not otherwise known, is Niebuhr's opinion. The 'Hellenica' have little merit as a history. The author was altogether deficient in that power of reflection and of penetrating to the nature of things, which mark the great works of Thucydides. It is generally a dry narrative of events, and contains little to move or affect, with the exception of a few incidents which are given more with than the usual detail. The parts also are not treated in their due proportions, and many important events are passed over briefly. Thus the only proper historical work of Xenophon, does not entitle him to the praise of being a good historical writer. It may be urged that the work was only a kind of Mémoires pour servir, as some have supposed, but it is to be supposed, that such a man as Xenophon, having the foundation of his model, must have shown a judgment and eloquence and the 'Anabasis.' This is not the case. The object is to show how events are connected and why some of them are successful or failures; and good government. 'Xenophon, throughout this work, is chiefly moral and picturesque, and the outward events are not connected with the moral and intellectual object of the in a suitable manner.
one of the many proofs of his aversion to the usages and the political constitution of his native city. The genuineness of the apologos, or conclusion of the work, has been doubted by some critics. Its object is to show that the Persians had greatly degenerated since the time of Cyrus. The 'Cyropaedia' is one of the most laboured of Xenophon's works, and contains his views on the training of youth. The character of a 'good prince' is an agreeable exposition of principles under the form of a history, and, like Xenophon's other treatises, it contains more of plain practical precepts, founded on observation and supported by good sense, than any profound views. The dialogue 'Hiero' is worthy of a pupil of Socrates. There is an English translation of the 'Cyropaedia' by Maurice Ashley Cоуper.

The 'Agesilicus' (Αγησίλαος) is a panegyric on Xenophon's friend, the Lacedaemonian king, another evidence of his Lacedaemonian proclivities. Cicero (Ad Fam. v. 12) says that he has in this panegyric surpassed all the statues that have been raised in honour of kings. Many modern critics have passed an unfavourable judgment on this work, and some maintain that it is the work of a sagan by the author at an age later. It has been described as a kind of cento made up of passages copied literally from the 'Hellenica' and other works of Xenophon.

The 'Hipparieous' (Ιππαρισσα) is a treatise on the conduct of cavalry, in which Xenophon gives instructions for the choice of cavalry men, and remarks on the duty of a commander of cavalry. There is internal evidence that this treatise was written at Athens, but there are different opinions as to the time when it was composed. The 'Horsemanship' (Χείρομηχανία) was written after the 'Hipparieous', to which reference is made at the end of this treatise. The author says that he has had much experience as a horseman, and is therefore qualified to give instruction to others. He speaks at the beginning of a work with which he is so much of the churchman, he coincides, and he professes to supply some of his omissions. This work is translated into English, and was printed by Henry Denham, London, 1884, 4to.

The 'Cynegeticus' (Κυνηγικά) is a treatise on hunting, a sport which Xenophon was fond of, and which contained some considerable observations. It contains many excellent remarks on dogs, on the various kinds of game, and the mode of taking them. [Arrian.]

The treatises on the Republics of Sparta and Athens were not always recognized as genuine works of Xenophon, but modern writers have adopted this opinion. But there is nothing in them which can be urged against Xenophon's authorship. They show his attachment to Spartan institutions, and his dislike of democracy. There is an English translation of the Republic of Athens, by James Morris, London, 1794, 8vo.

The treatise on the 'Revenues of Athens' (Τιμαι της περιφέρειας) has for its object to show how the revenues of Athens, and especially those derived from the mines, may be increased. The treatise on society and the state has been made subject to the maintenance of the poor citizens and all other purposes, without requiring contributions from the allies and subject states. The matter of this treatise is discussed by Böeckh, in his work on the 'Public Economy of Athens.' This treatise was translated into English by Walter Mapc, 1927, 8vo., and reprinted in Moyle's whole works.

The 'Memorabilia of Socrates,' in four books ('Ἀμνομαζέματα Ὁσκρατείς'), is the chief philosophical work of Xenophon. He defends his master against the charges of his enemies, but interrupting the train of his arguments he introduces Socrates after his fashion as developing and inculcating various moral truths. The tendency of the work is entirely practical, and it may be true, as some writers maintain, that Xenophon has exhibited a multitude of Socrates in manner more conformable to his own notions than in the full sense and spirit of the Socratic method. But Xenophon was a hearer of Socrates, lived for a long time in terms of intimacy with him, and as he was an eyewitness to the memory of his master, and certainly had no pretensions to originality himself as a thinker, we may assume that the matter of the 'Memorabilia' is genuine, that the author has exhibited a portion of the moral and intellectual character of the master, such passages as are such as suited his taste; and that we have in this work as genuine a picture of Socrates as his pupil Xenophon could make. There is an English translation of the 'Memorabilia' and the 'Apology for Socrates,' by Sir J. Fielding. The 'Apology' ('Ἀπολογία Σωκρατείς τοῦ Ὀσκρατέως') is not, as the title imports, the defence which Socrates made on his trial, but it contains the speech which determined him to prefer death rather than humble himself to ask for his life from his prejudiced judges. Vulcain and others do not allow that to be Xenophon's work, the speeches of Ogy and Ocy are worthy of him; but if a man is to lose the discredit of a bad work simply because he has written better, many persons may disown their own books. The 'Apology' is a trivial performance, but Xenophon did write it, and it is an apule in the long run. The 'Symposium,' or 'Banquet of the Philosophers' ('Συμπόσιον'), has for its object the definition of the character of Socrates. It is in the form of a dialogue between Socrates, Antiphanes, Critobulus, and others, at the house of Critias. It contains a subject of love and friendship. It is an ancient tradition that Xenophon wrote this work after the 'Symposium' of Plato, and that he designed to correct the views of Socrates, as given by Plato. Böeckh thinks that Xenophon wrote his 'Symposium' after receiving from Xenophon that he was an admirer of Socrates and that his purpose was to exhibit the ideal of a man in the person of Socrates. Ast is of the same opinion, and thinks that the 'Symposium' is a real work of Xenophon. There is a translation of the 'Symposium' by James Welles, M.D., 1710, and reprinted in 1780.

The 'Iris' (Ηυρίς ή ρανάκτρο) is a dialogue between Hiero, tyrant of Syracuse, and the poet Simonides. The tyrant describes the dangers and vexations incident to the possession of power ('τέρατα') was the title of the work, written for the tranquility of the private man. The poet shows that the tyrant has it in his power to oblige one person or private individuals can, and he offers some suggestions as to the best mode of using power and gain; and to which the public welfare is the end. The 'Iris' has considerable merit, and it is observed that it savours of the school of Socrates more than any other of Xenophon's works. There is a translation of this work attributed to Queen Elizabeth, but no authority on what authority. It first appeared in 1743, 8vo., in 'Miscellaneous Correspondence,' and the title is 'A Translation of a Dialogue out of Xenophon in Greek, between Hiero, a king, and some persons, and Simonides, a poet, as touching the life of a Tyrant.' Another translation also appeared in 1703, 8vo., which is attributed to the Rev. R. Graves, who translated Marcus Antoninus.

The 'Oeconomica' ('Οικονομικά') is a discourse on the management of a household and on agriculture, begun by Socrates, and used by Xenophon. It speaks of Cyrus the Younger, and his love for horses. This passage was written after the death of Cyrus, and Xenophon's work probably belongs to a later period of Xenophon's life, though Socrates is introduced as the author of the panegyric of Cyrus. It is a confirmation of the authorship of the 'Anaebasis' being rightly assigned to Xenophon, that he speaks of Cyrus, his character, and the in the same manner, and almost in the same words, as he is used in 'Anaebasis,' 'Oeconomica,' c. 1, and it may be supposed that the dialogue was written between Ischomachus and his wife on the duty of a wife, which consists in the proper management of the house; it is the husband's business to look after the financial affairs, and to apply it to the uses of the house. In the husband's employment, as here represented, is agreeable in a country where slaves are the labourers; but the part of married life will suit every condition. There is an opinion from this excellent writer that the husband's employment is at home; that the object of marriage is the happiness of the husband and wife, the prosecution of chil-
several English translations. The first is by Gentian Hervet, London, 1534, 8vo., which has been reprinted several times. There is also a translation by Robert Bradley, F.R.S., London, 1727, 8vo.

The general character of Xenophon may be estimated from this brief sketch of his life and writings. Before we leap upon him all the abuse which some modern writers have done, we ought to have the facts of his life with sufficient minuteness to enable us to judge of every part of it. He did not like the democracy of his native city, and he may have been glad of the opportunity of leaving Athens which the invitation of Proxenus offered. In Hellenic affairs, he was one of the leaders of the expedition of Cyrus; though it is very probable that he was blamed for it at Athens, and supposed to have been well acquainted with the design of Cyrus from the first, and it is certain that he accompanied the campaign of Aristobulus, the Lacedaemonian, after the campaign in Thrace, was well calculated to add to the jealousy of the Athenians, and his native city cannot be charged with more than her usual severity in banishing him for his part in the experiment. It is subhanced to fit the turbulence of the Athenians. He was a religious man, no, as we are now pleased to term it, a superstitious man. He believed in the religion of his country, and was scrupulous in preserving and enforcing the observance of the sacred ceremonies. He did not, however, give up his studies and upon them as manifestations of the deity. His philosophy was the practical: it had reference to actual life, and in all practical matters and everything that concerns the ordinary conduct of human life he shows good sense and feeling. He was an admirable man, who could express with propriety and in an agreeable manner whatever he had to say. As a writer he deserves the praise of perspicuity and ease, and for these qualities he has in all ages been justly admired. As an historian he is infinitely below Thucydides; he had no depth of reflection, no great insight into the fundamental principles of society. His 'Hellenica,' his only historical effort, would not have preserved his name, except for the importance of the narratives, and for the interest of many of the historical records. His 'Anabasis' derives its interest from the circumstances of that memorable retreat, and the name of Xenophon is thus connected with an event which exposed to the Greeks the weakness of the Persian empire, and by which they became familiar with the genius of the genius of men and the triumphs of Alexander. The narrative of the retreat may be compared with Herodotus for the minute detail of well selected facts, the simplicity of the narration, and the general clearness of the whole. But it is the narrative which is the best of the work, not the text, and in some cases the author's memory or his notes may have deceived him. The 'Anabasis' is a work of the kind which few men have had the opportunity of writing, and there is no work in any language in which personal adventure and the conduct of a race are treated with more harmoniously and agreeably combined.

The works of Xenophon, which are called philosophical, should be entitled treatises on practical ethics and econo-
These observations occur in the first series of Mr. Swainson's Zoological Illustrations, and in his Classification of Birds the genus is, in effect, immediately followed by the subfamily of Sittinae, or Nuthatches.

XEREZ, or JEREZ, the name of a mountain in Portugal, and of several towns in Spain and South America. Xerez, a small town among the mountains, 31 miles east of Granada. There are iron-mines in the vicinity, and some considerable iron-works in the town. Population, in 1833, 1900.

XEREZ DE BADAJOZ, more generally known by the name of XEREZ DE LOS CABALLEROS, a town of Estremadura, 34 miles south of Badajoz. Population, in 1833, 9000. It is a walled town, and contained before the last revolution nine convents and two hospitals. There is a considerable trade in cattle, and manufactories of cloth, leather, hats, pottery, and soap. There are silver and sulphur mines in the neighbourhood. The town is called De los Caballeros from its having belonged at one time to the Templars. Basco Nuñez de Balbon, the first who crossed the isthmus of Central America to the Pacific, was a native of Xerez de los Caballeros.

XEREZ DE LA FRONTERA, the name of a town situated in 36° 41' N. lat. and 6° 7' W. long. It is about a mile and a half distant from the right bank of the Guadalete, on the high road from Cadiz to Seville; 12 miles north-east of the former city, and 463 miles south-south-east of the latter. The population was understood to amount to 31,000 souls in 1833. The old town, inclosed within the walls, has narrow and crooked streets; those of the new town, outside, are broad and regular. There are eight parish churches. Before the last revolution there were eleven convents for men and seven for women. There are in the town one college, two free-schools, four hospitals, one hospital for orphans and another for foundlings, and a public granary. There are no manufactories, except for articles consumed by the inhabitants. The only trade of Xerez is in the wine of the surrounding district, the well-known Sherry, of which 450,000 arrobas have been produced in a good year. The inferior wines are consumed in the district; the sorts able to bear exportation are almost all sent to England. The magazines of the wine-merchants are remarkable for their extent. The olive was formerly cultivated to a great extent in the neighbourhood of Xerez, but this branch of agricultural industry has declined of late years. Considerable attention is paid to keeping up the race of Andalusian horses. The salt-works and sulphur springs of Jiganes are 31 miles south-east from the town, on the same bank of the Guadalete. Xerez received the distinctive epithet dela Fe etc. to distinguish it from other towns of the same name in the interior. Mihanò mentions that the name Xerez was believed to be a Moorish corruption of the name of one of the tribes which inhabited the district in the time of the Romans. Xerez de la Frontera is supplied by some to stand on the site of the ancient Asta Regia, others that place that at Meza de Asta, between the two three miles distant. Thomas de Moda, general of cavalry, was a native of Xerez.

The name of Xerez de la Frontera has been given to 1. a small town of Brazil, in the province of Rio Grande, to the east of Paraguay, now in the 2. a small town of Central America, in the states of Durus and district of Tegucipul, on the river Xerez, not from its mouth in the Gulf of Fonseca, near a carara; but now exhausted gold-mine in a country which produces much coca and indigo.

(Mihanò, Diccionario Geograpfo-estadistico de España y Portugal; Dictionnaire Geographique Universel.)

XERXES I. (379-479 B.C.), king of Persia, succeeded to the throne his father Darius, the son of Hystaspes. Darius was raised to the throne, Darius had three sons by his a daughter of Gobryas, of whom the eldest was Arab, zanes. After he became king, he had four sons by Shah the daughter of Cyrus, of whom Xerxes was the son. Darius appointed Xerxes his successor.

Darius died during his preparations for war against the Egyptians and the Athenians. In the second year of his father's death, Xerxes marched against Egypt, which had revolted in the time of Darius. He reduced to obedience and gave the administration of his brother Aesmenehis. He next employed himself for two full years in making preparations for his Greek expedition. The immense force which was assembled for this purpose was collected from every part of the Persian dominions. The fleet was supplied from Egypt, Cypria, Cilicia, and other maritime parts which were within the limits of the Persian government. Xerxes also entered into negotiations with the Carthaginians, who engaged to attack the Greek cities of Sicily and Italy, while the Persian king invaded Greece.

In the autumn of B.C. 481, Xerxes arrived at Sardis, capital of the Persians in the west, and he wintered there. In the spring he advanced to the Hellespont with all his forces, and encamped at Abydos, which was the first bridge that was made was destroyed by a storm which the king ordered that three hundred boats of the lash should be inflicted on the rebellious Hellespont. The superintendents of the work had their heads cut off out of their pains. The bridge was never built, which is minutely described by Herodotus (vii. 36). Xerxes army was seven whole days and nights in crossing to bridge from Abydos on the Asiatic to the European shore. The marsh was continued from the Hellespont through the Thracian Chersonese. The fleet did not enter the Hellespont, but took a western course along the Thracian coast. On arriving at the plain of Doriseus, which is near the sea and is traversed by the river Hebrus, Xerxes numbered his force. The ships took their station close to the shore. The infant Xerxes was sent to the Hellespont, and the mother was ascertained not by tale, but by measure; an inch was formed large enough to contain ten thousand men, and it was filled and emptied till the whole army was measured. (Herod., vii. 37.) After being thus arranged according to nations. Herodotus has left one of the most curious historical records that exists in his description of the various nations that composed this mighty force, and of their military equipment (vii. 61, 62). The cavalry amounted to 80,000 horse, and it was a grand army. The war-ships (πόλεμοι) were 1207. Herodotus has enumerated the several nations which supplied and manned the ships (vii. 89). From Doriseus Xerxes continued his march through Thrace. Herodotus, who has gone over the place, has described the march of the army with great distinctness. On reaching the isthmus which connects the mountain peninsula of Athos with the main land, the fleet avoided the circumnavigation which had
proved so dangerous to Mardonius in b.c. 492, by passing through the canal of Athos. This canal had been constructed by the Persians. It is described by Herodotus (vii. 22; see the article Axios). From Axios near the mouth of the Axios, the army marched to Thessalonica, now Saloniki, on the Axios. The fleet at last reached Sepias on the coast of Magnesia, in Thessaly, and there met the troops and provisions for Persians, Medes, and Sacae in each of them. The Persian commanders (περιπετευόμενοι), which Herodotus had not included in his former enumeration, were 3000, and, reckoning 80 to each, there would be 240,000 men in them. Thus the whole naval force held amount to 977,610, and the whole armament, both military and naval, would amount to 2,917,610 men, which includes 20,000 men, not before enumerated, camel-drivers and drivers of Libyan chariots. This is the amount of the force which passed over from Asia, and it amounts in all to the seven followers, the vessels that carried provisions, and the men on board these vessels. To this must be added 120 European vessels, containing 20,400 men, that joined the navy of Xerxes. The forces supplied by the Thracian tribes amounted from 20,000 to 500,000 men; thus the whole number of fighting men was 2,641,110. Herodotus considers that all the followers and those in the provision vessels would be more than the fighting men, but we will suppose them to be equal. Thus the whole naval force, according to Herodotus, conducted so many as far as Sepias and Thermopylae.

As to the number of women who followed to cook the provisions, and of eunuches and eunuchs, no one could tell the amount, nor that of the baggage of burden. The first calamity that befell this might have increased the number in the neighbourhood of Sepias, which caused great loss. At Artemisium there was an encounter between some of the Persian ships and those of the Greeks, in which the former made their escape from the latter. Scylla, finally, found itself stopped at the narrow pass of Thermopylae by Leonidas and his gallant band. The Persians sustained a heavy loss in endeavouring to force the pass, and they could not effect it till Epitaleis, a Mesian, showed the Persians the way to the rear of the Persians. Leonidas, who fell with his brave men after an obstinate conflict.

In the sea-fights off Artemisium, the Persians again sustained loss (Herod., viii. 11, &c.). The Persian army now grew in numbers, and they advanced before them. On entering Boeotia, they were joined by the Boeotians. A detachment was sent by Xerxes to attack the temple of Delphi, but the Persians sustained a signal defeat, and those who survived escaped into Boeotia. The Athenians marched to Artemisium, and joined the Persians to the island of Salamis, off the coast of Attica (Herod., viii. 40). The Athenians sent their females and slaves to Troezen, Aligia, and Salamin, and left their city to the mercy of the Persians, who, after burning Thespiae and Plataea, the only town in Boeotia that did not join them, entered Athens and destroyed it also. The Persians had occupied three months in their progress from the Hellespont to Athens. The fleet of Xerxes sailed from Histiaea in Asia, and, after the four-fifths of the Persians continued three days reached Phalerum in Attica. Notwithstanding the losses of the Persians, Herodotus considers that the land and sea force which reached Attica was as large as that which had reached Sepias and Thermopylae. The Graces were seen total is 3,500,000, and Herodotus gives 3,000,000 in the narrow passage between Salamis and the mainland. Xerxes, having resolved on an engagement, took his station on the shore of the mainland under Mount Egea, opposite to Salamis; and here he had the misfortune to see his mighty armament defeated and dispersed (Salamis; Thermopylae). B.c. 480. Shortly after the battle he retreated to the Hellespont, which he reached in forty-five days, and crossed over into Asia. He was attended as far as the Hellespont by Artabazus and Kersaspes. The Great King, who was left in Greece with the army, was defeated in the following year, B.c. 479, at Plataea in Boeotia by the combined Greeks, and on the same day the Greeks gained another victory over the Persians at Mycale in Ionia. This was followed by the siege and capture of Sestos on the Hellespont (b.c. 478), an event with which the history of Herodotus ends. It is said by Herodotus (viii. 106), that on the very day of the battle of Salamis, Gelon and Theron defeated, in Sicily, Hamilcar and his Carthaginian army, though the Greeks would have been successful both on land and at sea.

The Greeks continued the war against the Persians after the capture of Sestos. Little more is known of the personal history of Xerxes. He was murdered (b.c. 465) by Artabanus, and succeeded by his son Artaxerxes, called by the Greeks the Longimanus (Χαλκονόμης). Xerxes, it is said, by Herodotus, was cruel, vain, cowardly, and of feeble understanding. The great event of his reign is the invasion of Greece with his enormous army and fleet, of which we have in Herodotus (books vii.-ix.) a most minute account. The historian lived soon enough after the event to be able to collect trustworthy materials, and that he spared no pains is evident from his work. Much has been said on the large numbers of the arm and navy of Xerxes, as stated by Herodotus; but, incredible as they seem at first sight, an attentive consideration of the whole narrative of the historian will remove much of the doubt; at any rate, if the numbers are exaggerated, it is clear that Herodotus only followed his authorities.

XERXES II., king of Persia, succeeded his father Artaxerxes, the Longimanus, the Longimanus, in b.c. 465. He was assassinated after a short reign of a year, or, according to some accounts, two months, by Sogdianus, who succeeded him.

XILEMENIA, a genus of plants belonging to the natural order Oleanaceae. It was named in honour of Francis Xilemenius, a Spanish botanist, who gathered the plants and animals of New Spain. The species of this genus are trees or shrubs, usually armed with spines, and having alternate, ovate, or lanceolate exstipulate leaves. The calyx is small, permanent, 4-celled, hairy inside and covered at the base, valvate in uniovate structure, the stamens eight, with capillary filaments; the anthers 2-celled, fixed by the base; the ovary 4-celled and 4-seeded; the fruit a drupe, with one cell and a single seed. There are many species, some natives of America; the most remarkable is the X. americana. It has spiny branches, oblong entire leaves, the peduncles axillary and umbellate, the lower ones changed into spines. This plant is a shrub, attaining a height of eight feet, and is a native of South America. It produces a yellow fruit about the size of a pigeon's egg, which has a sweet acid taste, and is eaten by the natives. The flowers are small, of a greenish yellow colour inside, and sweet-scented. De Candolle describes two varieties: one, ovate oval, leaves prostrate, the other, in Guiana, with oblong leaves. (Don's Miller; Burnett's Outline.)

XILEMENIA, CARDINAL [Cissus].

XIPHIAS (έξιφιας), a fish, an inhabitant of the Mediterranean and Atlantic, occasionally visiting our coast, is a fish of the mackerel tribe, remarkable for its elongated upper jaw, which forms a sword-like weapon, whence its name. It measures from 10 to 15 feet in length. Its body is lengthened and covered with minute scales, the sword-forming flos of its length. On its back it bears a single long elevated dorsal fin. There are no central fins. The tail is keeled. The lower jaw is sharp; the mouth without teeth. The upper part of the fish is bluish black merging into silver below. The sword-fish is said to attack the whale, wounding it with its beak. There are many well authenticated instances of the planks of ships being perforated by the upper jaw of this powerful creature, which it has been said sometimes mistaken for the whole. Specimens of ship's timbers penetrated by its sword are preserved in many mansions. The Xiphas is mentioned by Aristotle (Hist. Anim., viii. 10), who notices the fact of its being used by fishers as food to be good eating. When very young the body is covered with small tubercles, which disappear before it attains the length of three feet. (See Yearell's British Fishes; and Cuvier and Valenciennes's Hist. Nat. des Poissons, vol. viii.)

XIPHIAS, a name for the constellation Dorado.

XIPHILINUS, JOANNES (Euphrasius), Patriarch of Constantinople, was of a noble family of Trebizond.
1066 he was made patriarch of Constantinople; he died in 1075. This Xiphilinus has often been confounded with his nephew. He is the author of an 'Oration on the Adoration of the Cross,' which was first published, in Greek and with a Latin version, in Greuter's work on the Cross, Ingolstadt, 1616, fol. Some other works of less importance are attributed to him, among which some Constitutions on matters of ecclesiastical discipline, two of which refer to betrothment, and are in the 'Jus Graeco-Romanum' of Leunclavius.

JOANNES, of Trapani (Tribizond), was the nephew of the Patriarch Xiphilinus. At the command of the emperor Michael Ducas, whose reign ended A.D. 1070, he made an Epitome of the history of Dion Cassius. The Epitome, as we now have it, commences at book, and dates down to the reign of Alexander Severus, A.D. 235. His work is not distributed like the original, but is divided into sections (γιγαντα), each of which comprises the history of an emperor. We can judge of his work by comparing it with those parts of Dion which are extant. He generally keeps to the expression of his author, but he omits what he considers not essential to the narrative. He has also generally omitted to mention the consuls, who are always recorded in the extant books of Dion, and thus he has done much towards confusing the chronology of the period. Like all other epitomes, it destroys the character of the original work; and it is worthless except as supplying the main historical facts of the larger part of Dion which is lost. Xiphilinus was a Christian.

The first edition of Xiphilinus was by R. Stephens, Paris, 1651, 4to, and these are the same as the second edition, the Latin version of G. Blanc. The edition of H. Stephens appeared in 1592, fol., with Blanc's translation, revised by Xylander. There is an English translation by Manning, London, 1704, Svo., of the Epitome of Xiphilinus.

XIPHORHYNCHUS, written by Mr. Swainson Ziphorhynchus, a genus of Certhiaires, or True creepers, according to that zoologist.

Subgeneric Character.—Bill lengthened, slender; both maxillaries considerably curved, typically falcated; the sides compressed from the nostrils. Wings rather lengthened; the second quill hardly shorter than the third. Tarsus short, slender, of equal length with the two external toes. Hinder toe shorter than the tarsus. Tongue cartilaginous, flat, as long as the bill.

Example, Xiphorhynchus procurvus.

XIPHOSOMA, Fitzinger's name for a genus of Serpents.

Cuvier remarks that his fifth section of the great genus Boa consists of those species which want fossas or little pits on the jaws, and have the muzzle furnished with slightly prominent plates cut obliquely from behind forwards, and truncate at the end so as to terminate in a wedge. Their body is very thickly covered, and surrounded by their back and sides. He observes that these are inhabitants of the East Indies, and may afford ground for including them in a distinct subgenus.

The species which he quotes are the Boa carinata of Schneider, or osculata of Oppel; and the Boa vipera of Shaw (Russel, pl. iv.). These two subdivisions form, he adds, the genus Xiphosoma of Fitzinger, Cenchris of Gray.

XIPHOSURA, the name by which M. Milne Edwards designates a subclase of crustaceans, which he arranges at the end of his system and next to the Scolar Turacaces.

M. Milne Edwards observes that the singular animals which compose this small group are so remote from all the other crustaceans, that some naturalists have been inclined to exclude them altogether from that class, and arrange them among the Arachnida, and that in entirely rejecting this opinion it becomes necessary to isolate them as much as possible, and to form a particular subclass, which is connected with that of the Branchiopoda and that of the Tailorcrabs, but is distinguished from those crustaceans and all the other animals of the same class by the character of its organisation. The natural position of these Xiphosures should, in the opinion of M. Milne Edwards, have been near the Branchiopods, but he has preferred the place which he has assigned to them, in order that he might not break the connection which unites all the Maxillated Crustaceans.

* They are circular; see post, p. 608. • Seven.
a claw with equal branches: this is sometimes the same in the male; but in some species of Limulus this sort of hand is wanting in the feet of the second and third pair, the prolongation representing the immovable finger not being developed. The sixth pair of feet differs much from the preceding: their basal joint is larger, terminates on the internal side in a toothed surface bearing some resemblance to that of a grinding mandible, and carries at its external angle a fabeliform appendage. Sometimes here exists a small lamellar appendage at the extremity of the fourth joint, and the next joint carries its anterior border many of those subfoliaceous and elongated laminae which hide nearly the succeeding joint, as well as the small didactylous hand which terminates it. Lastly, between the base of these feet, at the posterior part of the horns, are two small lamellar pieces which are obtuse at their ends and furnished with spines, which seem to be the edges of a seventh pair of limbs. The abdomen is hollowed out into a rather deep cavity, which is very analogous to that in Sphaeroma and many other Isopoda. In his cavity are lodged the abdominal false feet and the branchia fixed to their posterior surface. There are six pairs of these members, but the most anterior are not distinct and are united on the median line, as in the Nereis or Amphiura, as a large foliaceous and nearly circular valve, but in the next anterior, and which entirely covers the succeeding false feet in each half of this appendage are to be distinguished one or two basal pieces and two terminal laminae, which represent the branches which ordinarily terminate these organs: one of these pieces, situated near the median line, is small, and separated from that of the opposite side by a fissure; the other is very large and, finally, on the superior or posterior surface of this first pair of false feet the two orifices of generation are found. The succeeding false feet are equally foliaceous, and united on the median line throughout the whole extent of their basal piece; but the two branches which terminate each of these organs are free and more developed. The internal branch is composed of two joints, the first of which is quadrilateral and elongated, the second foliaceous and oval. The external branch is represented by a very wide lamina, which is rounded externally, and resembles that of the operculum. The two external thirds of the posterior surface of the basal portion of these limbs are occupied by a great gill formed of a considerable number of laminae, or rather of cutaneous folds, disposed transversely, and piled one on the other like the leaves of a book. These leaves adhere to the false feet throughout the length of their base or anterior border, and are free in the rest of their extent. They are triangular, with a curved border, and increase in size from the upper extremity of the branch to its base, so as to give to this last the form of a pyramid, the posterior ridge of which is curved, the two free surfaces convex, and the base rounded. The free edge of each leaf is furnished with a small hony band, destined to sustain it, but throughout the rest of their extent these folds are membranous: there are about one hundred and fifty of them in each of the first pair of gills, and a few less in the succeeding gills; the last has only about one hundred and thirty.

Limulus Moluccorum, reduced one-fourth, and seen from above.
Position of the two smooth eyes; b, lateral compound eyes; c, respiratory apertures.

The mouth, situated towards the posterior third of the lower surface of the cephalothoracic backer, is surrounded, as has already been noticed, by the feet, the basillary joint or lamina, which is armed with spines or
teeth, and disposed so as to serve for the work of mastication. This aperture is infundibuliform, and continued with the digestive tube, which is directed at first directly forward, then curves upwards and backwards, and proceeds in a direct line to the extremity of the abdominal bucker, where it presents anew a small curvature in its course to the anus. The first portion of this canal, directed forwards and upwards, the intestine, constitutes the occluded tube; it is narrow, rather long, and furnished internally with longitudinal plait. The stomach is represented by the curved and anterior portion of this same tube; it is small and directed vertically; its walls are very fleshly, and puckered (trabeculate), internally; an internal fleshy, feathery, and from the oesophagus, and its pyloric extremity advances in form of a cone in the cavity of the intestine, so as to constitute a species of funnel. The third portion of the intestinal tube occupies nearly the whole length of the body, and represents the duodenum, or cylindrical ventricle: it is cylindrical, straight, and has towards its two extremities some transverse folds of the internal membrane, and more or less projecting papillae. On each side a little above the level of the mouth, are two small circular orifices, which belong to the biliary apparatus, and its posterior extremity is suddenly contracted in order to its continuation with the fourth portion of the digestive tube, which may be considered as the intestina rectum. It is very short, plaited longitudinally, and is directed downwards and externally in order to reach the anus, which is situated in front of the insertion of the caudal sword. The liver fills in the cephalo-thorax the space situated between the intestine and the muscles of the foot; it extends also into the median chamber, and is composed of two orifices, which are continued with the excretory conduits, the four trunks of which open in the anterior part of the duodenum.

The heart bears much resemblance to that of the Spiders, (Struxostoros, p. 83.) It is a long dorsal vessel with fleshy walls, which present on each side several transverse apertures furnished with valves, and which give origin to various arteries.

The nervous system consists in a medullary ring which surrounds the oesophagus; it gives origin to the cephalo-thoracic nerves, and is continued backwards with a stout chord, from the posterior part of which the abdominal nerves spring.

The organs of generation open externally by the apertures of the base of the first pair of false feet. In the females these orifices each communicate with an oviduct, which when arrived in the thorax is divided into two branches, the ramifications of which constitute the ovary and embrace the liver. In the male, in place of the ovary, there exists a spermathecal organ. (Histoire Naturelle des Crustacés, 1840.)

Such is the statement given by M. Milne Edwards of the organization of this highly interesting form.

But, in his "Human thoracic Lectures" (1843), he has touched upon certain points, for whose detailed illustration zoologists are anxiously looking, especially with regard to the development of the nervous system.

The Professor states that the Xiphosura, typified by the Limulus, or Molucca crab, have the head and thorax more completely blended together than in the true crabs, which resemble in the general form of the body; but that they are peculiarly distinguished from all other crustacea by having the office of jaws performed by the first joint of the thorax, which Surrounds the mouth. The cephalo-thoracic segment is, he remarks, protected above and laterally by an expanded crescentic shield obscurer divided by two longitudinal impressions into three lobes, supporting the organs of vision on their highest part. The body of the segments of the body of the limbs is also divided into three lobes, which are blended, he observes, into three trilobate cylindric piece, their original separation being indicated by the branchial fissures, and the number of the segments by the number of the trilobate piece. When the abdomen is also divided, he adds, into three trilobate cylindric piece, with the original separation being indicated by the branchial fissures, and the number of the segments by the number of the trilobate piece.

The termination of the intestine beneath the last segment of the second division of the body of the Limulus presents, in Professor Owen's opinion, and correctly, as we think, that division to answer to the abdomen in the Japanese carp, but admitting the immensely large eye of the same segment, not more than sixteen segments can, he remarks, be determined by the appendages to enter into the composition of the entire crust of the Limulus, including the sword-shaped appendage, which is analogie in the Japanese carp, to the last post-segment of the higher crustacea, and consists of a single podal segment.

Professor Owen then adverts to the small Entomostoma, in which the number of the thoracic and abdominal segments is less than that in the Limulus, and adduces as an example the Branchipus stagnalis (Brachiopoda, p. 343), which has eleven thoracic segments or nine abdominal or caudal rings, besides a distinct head protected by a thoracic shield. In the Isora, in which the head is very indicated, and the abdomen is divided among the Entomostoma, to the extent and in the form of a broad shell enveloping the whole body, the number of thoracic and abdominal segments exceeds that in the Limulus, or shows more than one podal segment.

These and other observations of the Professor shows the segments of the crustacea are highly interesting when considered with reference to a race of that class who live in water but have no living analogue; and he thus points out the value of this part of their construction as applicable to the subject:

'In the species of Entomostoma and Malacostraca in the number of the segments of the body is of the first importance in determining the affinities of the class. Amongst the various remarkable animals which were almost the sole representatives of the present class in the periods which intervened between the deposition of the earliest fossiliferous strata to the origin of the coal formation. They appear to have been abundant. Of these, the parts of the body only of their body-segments is yet known; but the second species, which is united together to form a distinct head, thorax, abdomen or tail. The head is formed by a large circular or crescent-shaped shield; the thorax consists of the second to fifteen segments, of which each bears a row of fleshy processes. The abdomen are very similar to each other, and gradually increase in size. They are divided by two longitudinal rows into three lobes. The head supports a pair of compound eyes situated near the sides, like the large pair of eyes in the Limulus, which they resemble in size and structure.

'Malacostraca are divided into two groups, according to the attachment of the eyes: those with immovable sessile eyes form the Epithlotos; those with pedunculated eyes, the Podophthalma. In the latter the eyes are directed to the sides, and the second to fifteen segments of the body are divided into three lobes. The Malacostraca resemble the Tribolites in the non-confluence and uniformity of the segments of the abdomen, which in the Limulus is divided into three lobes. Bopyrus, have the tergal area of the segments divided, but they exceed not the characteristic number in the Malacostraca, and the seven rings of the thorax are only indicated in each by the seven pairs of antennae which they support, although these are very small in size and structure. The seven to fifteen and seven abdomen segments are more distinctly characterized.'

With regard to the nervous system and sense organs, Professor Owen has alluded to Cuvier's description of the par of the organization in the common crab. Mr. Snell illustrated dissections and beautiful plates of the eyes, and the able display of the corresponding structures in the Milia by Audouin and Edwards, observations on the molluscous and crustacea. The head is also divided into three lobes, the outer lobe of which bears the compound eyes, and the second division is completely enveloped by the cuticle, and the third division is connected with the posterior division of the nervous system, but with interesting modifications, has been described by Professor van der Hoeven in the Limulus, or King-crab, the most gigantic form of the Entomostracous tribe, and probably the only existing genus from which we may gain a glimpse into the organization of the extinct Tribolitie crustacea. Professor Owen was therefore induced to publish the well-preserved specimens of Limulus, given to the College of Surgeons in London, by Mr. Booth, of Boston. Bopyrus, in the College, whose beautiful dissections and preparative will be found in the museum of the College. The details of the nervous system so displayed, together with the

* Boo, Longman & Co.
of the anatomy of the Limulus, will be published by the council of the college.

Professor Owen observes in his lectures that the large lateral compound eyes of this crustacean are sessile. The cornea, he proceeds to state, is divided into a considerable number of small circumscribed masses of food to the microscope, to an ocellus; and the optic nerve, after its long course as a simple chord without forming a ganglion, divides near the eye into a pene of fine filaments, which severally receive the impressions from their respective ocelli, of the aggregate of which the lateral compound eye is composed:

the two small simple median eyes, which are almost in contact, command the space before the head which is out of the range of the large compound eye. Each simple eye, he further informs us, receives its distinct nerve from the median eye or the lateral eye, according as which of them is nearer to the position of the respective four eyes; this being the reason why a corresponding nerve, with four eyes severally on it, is only four cilia long.

In the sessile eyes of the Edriopthalmus, as, for example, in the Serolina, says Professor Owen in continuation, the inner layer only of the cornea is divided into hexagonal facets, corresponding with the number of the rays, in which the lenses of the compound eye are.

The Tribolites the cornea presents the same subdivided surface as in the Limulus; and the position of the two eyes agrees with that of the corresponding compound pair in the larger crustaceans, Entomostraca, and so in the Tribolites. In the Anasopus caudatus the cornea is divided into at least 400 compartments, each supporting a circular prominence; its general form is that of a frustum of a cone incomplete towards the middle line, and with its base placed above, as has already been observed in other directions, that where the distinct vision of one eye causes that of the other begins. In the mandibulates crustaceans, distinguished by having their compound eyes supported on movable peduncles, the form of the corneal acetabulum is somewhat similar in the, for example, in the hermit and common crabs. There is a conical crystalline lens behind each facet imbedded in a small fleshy humour, upon which the optic filament expands, and each ocellus is lodged in a pigmental cell, which likewise expands in the same manner when the cornea is forced together by the passage of the optic nerve. In the Podophthalmous Crustacea there is generally a spacious furrow or groove in the head, in which the lenses of the compound eye are, and which is termed the orbit. In one or two species the eye-stalks project beyond the margins of the carapace.

The same acute observer, speaking of the organs of vision of these large crustaceans, which were probably co- existed with Tribolites, remarks that the Limuli differ from all other ringed crustaceans in their organs of mastectomy, which are modified hard joints of the five posterior pairs of legs: the first pair is the leg, the first pair is the leg, rudimentary in both our lepidopods, and the median part of the body is to be made by the entomostraceous genus pure in which however the labium is truncated. A few of the largest organized crustaceans, as Callinus, Nymphon, and Phrygonocon, obtain their aliment, he adds, like the crabs.

After referring to the structure of the mouth in the Falocrosteus Crustacea, and pointing out that the alimentary canal is most simple in the Suctoral Crustacea, which it presents no noticeable difference from that in the head, but becomes more of the horizontal is localized and better developed, he thus describes this part of the organization in Limulus —

In the Limulus the mouth is nearly in the centre of the inferior surface of the great cephalo-thoracic appendages. It consists in a small chitinous tube which is simple and does not continue forward, and expands into a stomach, which is situated at the anterior part of the head. This organ is abruptly bent upon itself upwards and backwards, and is continued by a gradual diminution of diameter, as appears from the internal view, into the intestine, with a slight vertical bend, to the base of the penultimate abdominal segment. When we examine the interior of the alimentary tract, the distinction between the stomach and intestine is effected, as Van der Hoeven has shown, by a conical valvarly pylorus, which projects into the commencement of the intestine. The stomach is lined by a very dense and corrugated horn membrane. The hepatic mass, which, with the generative glands, fills the greater part of the cephalo-thoracic appendages, pours its secretion into the commencement of the intestine by two ducts on each side. (Prep. No. 477, A.)

In the heart of the Crustacea, Professor Owen remarks, we may trace a gradational series of forms, from the bivalved median dorsal vessel, to the short, broad, and compact muscular ventricle in the lobster and the crab. In all the Crustacea, he reminds us, as in all the other articulate animals, the heart is situated immediately beneath the skin of the back, above the intestinal tube, and is retained in situ bisecting the body. In most of the species, the lower, elongated, slender, many-jointed species of the Edriopthalmous Crustacea the heart, he observes, presents its vesiform character: it is broadest and most compact in the crab.

In this series, continues Professor Owen, we may trace a general correspondence in the progressive development of the vascular as of the nervous system, concomitant with the concentration of the external segments, and the progressive compactness in the form of the entire body. But there is a remarkable exception to this concomitant progress in the Limulus, indicative, with the general condition of the instruments of locomotion and respiration, of the essentially inferior grade of organization of that genus, and which observes more especially the last remnant of the once extensive group of Tribolite Crustacea which swarmed in the seas of the antediluvian periods of the earth's history.

We have seen, continues the Professor, in the compact and broad existing representatives of the Gigas, of the Entomostracous Crustacea, that the nerve-mass exhibits a concentration of its principal central mass around the mouth, analogous to the condition in the common crab, but with a ganglion large double chord continuing from it. The heart however continues to retain its independent character, distinctly formed as a series of tubes, into which the same degree of concentration: it remains an elongated fusiform tube, extending parallel with the intestine from the pylorus to the rectum: it is contained in a pericardium with thin membranous walls, formed by the central sinus of the venous system, and it receives the blood from that sinus and from the branchial veins by a series of from seven to ten lateral vertical slits, defended by valves as in the higher crustacea.

An aortic trunk proceeds from each artery through the notch of this heart, the arteries, which, as the aortic trunk, divides and immediately divides into three branches. The middle and smallest branch passes forwards to the anterior edge of the cephalic shield, following the curve of its middle line, and supplying the small median ocelli in its course. The largest branch arches round to the side of the stomach and the esophagus, giving branches to both those parts and to the intestine, and becoming intimately united with the neuromerium of the cephalopagous nervous collar. They unite at the posterior part of that collar, and form a single vessel, which accompanies the abdominal nervous ganglion chord to its posterior bifurcation, where the vessel again divides. Throughout all this course the arterial is so closely connected with the nervous system as to be scarcely separable or distinguishable from it. The branches of both the arterial and the nervous trunks, which accompany each other, may be defined and studied apart.

The posterior series is chiefly destined for the support of the sword-like tail of the Limulus: the final part of its great cephalo-thoracic appendages, which is fixed to the strong inflections of that appendage. The arterial is mixed with the venous blood in the heart, and is propelled in that mixed condition throughout the body, in the Limulus as in the lobster.

With regard to the reproductive apparatus, Professor Owen observes that most of the small Entomostracous carry the impregnated ovum in appended ovicases, like those of the Lernae. These sacs are not developed, he remarks, in the Limulus, which also differs from the smaller Entomostracous inasmuch as the ovarian mass is the ovicase and processes with those of the liver: the oviducts, he adds, form more frequent communications with each other than in the higher crustacea, but ultimately terminate, like the vasa deferentia, by two distinct but coalescent orifices.

* Van der Hoeven, p. 12, f. 9.
on the back part of the first abdominal lamelliform appendage.

**Metamorphosis.**

M. Milne Edwards has shown that the Xiphosures undergo in their youth considerable changes of form. At first there is no sword-like or styliiform tail, which in the adult Limulus equals, at least, the rest of the body in length; their abdominal bucculae are rounded posteriorly, and the last pairs of false feet are not developed. M. Milne Edwards observed that this is true of the embryos on the point of exclusion from the egg, which period the abdomen supports only three pairs of appendages.

**Geographical Distribution and Habits.**

The Xiphosures inhabit the sea, and sometimes come upon the sandy beaches. They are found in the Indian and Japanese seas, and in the Atlantic, on the coasts of North America; but they do not appear to have a higher range than the 44th degree of N. lat., and seem confined to the northern hemisphere. Their food consists of animal substances; and when stranded, they often bury themselves in the sand as a protection against the heat of the sun, which is soon fatal to them.

**Arrangement.**

The only genus is Limulus. Müller.

M. Milne Edwards remarks that Leach, it is true, has restricted this generic name to those species the whole of whose appendages are lamelliform, and has proposed a new genus, under the designation of Tachypleus, for those whose anterior feet are monadactylous; but, he observes, it is now well known that this last character is only met with in the male of certain Limuli, and does not coincide with other peculiarities of an important character, so that it does not appear a sufficient basis on which to found a generic division. M. Milne Edwards thus arranges the only recent species known, five in number.

1. Species whose second and third pairs of jaw-feet (first pairs of Latreille) are monadactylous in the male, and in which the movable spines of the lateral border of the abdomen are of two sorts, namely, very long and very short.

**Limulus moluccanus.**—Description.—Cephalo-thoracic bucculae regularly rounded anteriorly in both sexes, and above showing three rows of small spiniform points, situated one on the median crest, the others on the crests which separate the occipital region from the lateral regions; the posterior and lateral borders of the abdomen finely dentitiate. The abdominal buccula smooth above, and terminated by two very short teeth, the internal border of which is very long, and the external border (comprehended between the point and the insertion of the last spine) very short; tooth of the lateral-abdominal border more acute, is situated towards the middle of that border; movable spines of the lateral-posterior border moderate, and all nearly of the same length in the male; the three first rather long in the female; but the three last extremely short, and much wider than they are long. Caudal stylet triangular, spiny on its upper border, and slightly concave on its inferior surface. Last pair of jaw-feet turned towards the end with four elongated appendages, which are lamellated, flattened, and subulate.

(M. E.)

This is the Cancer moluccanus of Clusius; Cancer per versus of Rumphius; Limulus Polyphemus of Fabricius; Limulus gigas of Müller; and Limulus moluccanus of Latreille.

M. Milne Edwards is of opinion that Leach’s Limulus Latreillii probably belongs to this species, as well as Limulus tridentatus of the same author.

**Limulus moluccanus** is apparently the Cancer figured by Bonnitz in the fifth book of his 'Natural and Medical History of the East Indies,' p. 85, in which he notices its sword-like appendage, and states that if any incautious fisherman is wounded by it, the pain is like that caused by a scorpion, adding, that its flesh is not so delicate as that of the other crabs. The chapter is headed by the following verse, which refers to the painful wound inflicted by the tail:

"Quodque cancer moluccanus facat, Petitur..."

This is an extract from the 'Natural and Medical History of the East Indies,' p. 85, in which he notices its sword-like appendage, and states that if any incautious fisherman is wounded by it, the pain is like that caused by a scorpion, adding, that its flesh is not so delicate as that of the other crabs. The chapter is headed by the following verse, which refers to the painful wound inflicted by the tail:

"Quodque cancer moluccanus facat, Petitur..."

**Limulus virgatesus.** M. Milne Edwards states that this species, the female only of which is known to him, bears a strong resemblance to Limulus moluccanus, but is distinguished from it by the considerable length of the posterior foot, the penultimate joint of which is extremely short, and surrounded at its base with seven spines, which instead of being flat, very much elongated, and rather wide, are rounded, conic, and very much pointed. The four last pairs of feet were broken in the only individual which M. Milne Edwards had examined, so that he could not judge the character indicated by Latreille, the name and describer of the species, drawn from the monadactylous formation of the second pair of feet. It is also worthy of note, M. Milne Edwards adds, that the cephalo-thoracic buccula is less convex than in the preceding species.

The same author observes that the Limulus prae-" "

L. Limulus, second metamorphosis. the Paris museum under the name of Limulus kermacki, Latreille. This species, having the teeth or posterior angles of the abdomen bucculae larger and more regularly triangular; the external border of these teeth being nearly as long as the internal border, and their base much less wider than the median between them, and occupied by the surface of the abdomen covered with small spines. The tooth of its latero-anterior border larger, and situated near that which separates border from the lateral-abdominal border; movable spines of the lateral-posterior border of the male are of the three first pairs very long, three last pairs very short, but sharp in the female. Caudal stylet triangular, and spiny on its borders. Frontalief of the male strongly notched and sinuous, so as to appear trilobal.

**Locality.**—Coasts of Japan, and probably of China.

This is the Keboto-gani (Helmet-crab) of the Japanese Un-kii, or Uni-do-gami of the Chinese.

2. Species in which the third pair of jaw-feet is uniformly in both sexes, and which have the movable spines of the latero-posterior border of the abdomen diminish gradually in length in both male and female.

a. Second pair of jaw-feet monadactylous in the male. Caudal stylet triangular and sharp on its upper border.

**Limulus Polyphemus.**—Description.—Cephalo-thoracic bucculae more convex than in the preceding species, preserving for a longer period the seven spines of the upper surface. Posterior spines of the abdomen large, and representing an equalilateral triangle, and being longer than they are wide at their base. Movable spines of the latero-posterior border more acute, and similar in both sexes; the three first pairs of the male the project more, the second diminishing speedily and the caudal stylet is less long. (M. E.)

**Locality.**—The Atlantic Ocean, coasts of North America, and the Antilles.

This is the Araneus marius of De Laet; Cancer moluccanus of Wormius; Monocerus Polyphemus of Linnaeus; but he confounds under this name both the Oriental American species; Limulus cyclops of Fabricius; Limulus Americanus of Leach; Polypus occidentalis of Marshall; and Limulus Polyphemus of Leach.

John de Laet, in his 'Novus Orbis' (1633), gives a fair figure of this species in the 10th chapter of his book, and states that the arms of the Indians (Ambosques) of Wijngaerdens Eylandt in North Holland, club, bow and arrows with which they sharpen with the crustaceous tail of the monstrous fish Sigur, Siguanou, or Araneus marius, by which name the Limulus there engraven is known to the natives and Dutchmen. De Laet gives a good description of this animal, and says that it loves the sandy shores, and is mostly taken at seastuaries, of various sizes, not a few having a tail exceeding a palm in length.

M. Milne Edwards observes that Limulus hannah, a variety of this species having the last median tooth of the upper surface of the abdomen more protruded than it is ordinarily to be seen in adults.

a a. All the jaw-feet cheliform in the male and as in the female: caudal stylet rounded above.
**Limbulus rotundicauda.**—Description.—Cephalothoracic exoskeleton wider than in the preceding species, less convex, and deprived of the series of small spines between the first teeth of its upper surface, but with a number of these spiniform points scattered on the occipital region; in its inner border about twice as large as the external border; its opisthosoma moveable nearly as in the preceding. Cephalothoracic exoskeleton with rounded borders. (M.E.X.)

Locality.—The Moluccas.

This is the *Cancer marinus pecurator* of Seba.

**Fossil Xiphosura.**

The fossil forms of this group, contemporaneous as some of them were with the Trilobites, to which they bear so strong a relationship, are among the most interesting fossils, *Limbulus triloboides*, Buckl., from the beds of Maine, and is a pl. 46 of the *Bridge-water Treatise*, is very trilobitic in appearance, and in the early state of the animal, before development of the caudal styly, the resemblance must have been still more striking; nor will it escape the notice of the paleontologist how, in the Rhenish beds, the number of the trilobites is furnished with a long caudal appendage.

Geological Distribution, &c.—*Limbulus*, as Dr. Buckland remarks in the work above noticed, has been found in the coal formation of Staffordshire and Derby, as well as in the Jurassic limestone of Aichstadt, near Apenheim, together with many other marine crustaceans of a higher order.

M. Milne Edwards notices the numerous species which have been recorded. That figured by Desmarest under the name of *Limulus appendens* (Mars. and Knorr) is found, he observes, in the lithographic slates of Solenhofen and Pappenheim. In M. Edwards' opinion approaches *Limulus longissimus* more than any other fossil species, but appears to have the latero-posterior borders more oblique. The cephalothoracic exoskeleton is not divided, and the abdomen wider, with its latero-anterior borders very short; as to the moveable spines, they are, i.e., remarks, six in number, and are all long and slender.

Other fossil Limuli have, M. Milne Edwards adds, been discovered, not only in this formation, but also in the muschelkalk and the Jurassic limestone, by Count R. Ram, who has given figures of them in the excellent work of Van der Hoeven on the Limuli; but M. Milne Edwards thinks it probable that these adductions have not been as decided, and sufficient to enable naturalists to assign specific characters to them, and he confines himself to observations that *Limulus intermedius*, Muntz, found at Solenhofen, and *Limulus brevicauda* (brevicaudatus), of the Jurassic limestone of Aichstadt, near Apenheim, with a very short appendage, and of which the abdomen, represents a rhomboid rather than a hexagon, its anterior border being nearly conformed with its latero-anterior borders. *Limulus ornatus* of the same author, in the opinion of M. Milne Edwards, appears to resemble the fossils more or less, and many other characters that are.

B. Xiphosura has been used by Fitzinger to designate a genus of Saurians arranged by Mr. Swainson as a *Genus of Agamid*. 

**Xorulio, or Jorullo,** is a volcano situated in the State of Durango, one of the United States of Mexico, in 21° 59' lat. and 101° 32' W. long. This volcano has risen out of the earth in modern times; and of its origin we have an account. The Monte Nuvo near Naples, which was blown in 1538 by a volcanic eruption, did not continue to exist longer in a volcanic state than seven years. From the extraordinary height and the total disappearance above the ballet of clouds, it is evident that it has become a mountain, and the scattered pyramids from which the volcano rests. In the small cones at the foot of the volcano balls of basalt are found, which are enclosed in hard clay lying in concentric layers; whence Humboldt infers that those volcanos which have become extinct have been the scene of revolutions. The two rivers mentioned above are at present lost under the lava, but on the western side of the Mal Pas there are now found some hot-springs, in which the thermometer rises to 105° Fahrenheit.

**Xylander, Gulelmi.**—Xylander's real name was Holzmann (Woodman), under the family name, in a short time after his birth, he changed into the elegant Greek form of Xylander. He was born at Augsburg, December 26, 1532, of poor parents. Xylander obtained the patronage of the Academy of Letters in 1570.
Wolfgang Relinger, a patrician of Augsburg, who procured him the necessary means for prosecuting his studies till he was received into the College of Augsburg, where he had a certain allowance, which was appropriated to a limited number of pupils. Thus we must form that as a boy he had shown great talent. In 1549 he went to Tübingen, and in 1556 to Basel. His studies were the mathematics and Greek and Latin literature. After the death of J. Micylius, in 1558, he was made Greek professor in Basel, but he was obliged to add to his means by his pen. He died in February, 1576, having shortened his life by his excessive labour, and, according to some accounts, by drinking. It is the statement of Jöcher that his salary as professor was insufficient, and that he was obliged to work for the booksellers; but in the 'Biographie Universelle' (art. 'Xylander', by Weiss) it is maintained that his salary was sufficient. If he was drunk and extravagant, it may very well have happened that he was always poor and glad to work for money. In the elegant verses prefixed to his translation of Dion Cassius, and placed at the end of his dedicatory epistle, he complains of his poverty. This dedication is dated November 1, 1558, and is the following year he was appointed professor at Heidelberg. The greater part of his works appeared after his appointment at Heidelberg. Xylander was also named by the elector palatine Frederic, secretary to the congregation at Maulbronn, which was held for the settlement of differences among the Protevangelists, and is said to have received money for his services from this prince, and also from the duke of Würtemberg. It seems probable that, with all these means and what he received for his literary labours, if he was poor after he went to Heidelberg, it must have been through his own improvidence.

Xylander's works are very numerous. A large part of them consists of translations from Greek and Latin authors.

His translations into Latin are:—1. Plutarch's 'De Republica'. Basel, 1553, 4to. 2. Strabo, accompanied with the Greek text, Basel, 1571, fol.; 3. 'The Chronicle of Cedrenus,' with the Greek text, Basel, 1565, fol.; 4. Tryphiodorus, in Latin verse; he is said to have made this version when he was sixteen years of age. 4. The work of Michael Psellus, and Chaucer's 'Canterbury Tales', translated by him notes, Basel, 1556, 8vo.; 5. The History of Dion Cassius, Basel, 1558, fol., with the Latin translation of Xiphilinus by W. Blance, which he corrected ['Xiphilinius'], 6. 'The Life of the Emperor Marcus Aurelius', translated by So- richi, 1598, 8vo.; Lyon, 1592, 12mo; 'Greek and Latin, Basel, 1568, 8vo.; To this last and corrected edition Xylander added the versions of Antoninus Liberalis, the work generally attributed to Apollonius Dysiscus, and which, Xylander, under the title of 'Antonini Liberalis Gaminge', defined:—Calyx coriaceus, 4-5-furrowed; petals 4 or 5, coriaceus; stamens 8-10, the filaments of which are joined into a tube, which is toothed at the apex, and bears anthers on the inside of the throat; the style about 1½ in. long, stigma bifid. One other species is also Xylander's, but differs from the above in being a 4-5-seeded; the seeds thick and without albumen.

Carapa Guineanensis, the Persoonia Guineensis of Willdenow, is a native of the forests of Guinea. It has the taste of leaves. The wood is coarse, coriaceous, and shining. The seeds of this tree yield an oil, which is extracted by the natives of Guinea by boiling and used by them for applying to the hair and anointing their bodies. The oil is thick and has a bitter taste, and attains a height of 4 or 5 feet, and, the trunk is used for making masts for small vessels. The fruit is about the size of an apple. The Caribbees call the tree Carna, the Caripus J-Antroba. C. Guineensis is a native of Sierra Leone, and the oil of the nut is used for making soap. C. Moluccensis, the Xylocarpus Granatum of Kema, a native of the Moluccas. It has 3 pairs of opposite, acute leaflets. It is called by the Cingaleses 'Gaha, and by the Tamuls 'Candulgre'. It has an extremely sweet taste. (Don's Miller; Lindley, Natural System.)

XYLOCOPA (that is, wood-eaters), a genus of the Lepidoptera family Scopuliplices,Late, or Anthophorides. It is characterized by the presence of several small, thick, light-colored hairs upon the hind legs of the females, which constitute pollen-brushes. The basal joint of the posterior tarsus usually exhibits its extremity angularly produced. They have no pollen-plates, and the abdomen is divided into a ventral pollen-labium. The two posterior tarsal joints of three perfect submarginal cells, the third joint of the antennae...
frequently long and elevate, being very slender at the base; the mouth is sometimes considerably developed. Notwithstanding the shortness of the wings and the comparative bulk of the body, these insects fly with much strength and activity, and with a loud buzzing noise.

The sexes are frequently (in many cases), both in colour and structure; the males in some having very long antennae, while in others the posterior femora are much thickened, and in a few the tarsi of the intermediate legs are furnished with curious brushes of hair. The face is frequently of a pale yellow colour. The females are usually of darker and more obscure colours than the males. They form their nests in crevices of old walls or in banks exposed to the sun. Their cells are composed of earth and are very smooth in the inside, and the mouth of the nest is closed with the same material.

The wings of the Xylocopa, or (as they are frequently termed) carpenter-bees, are most frequently (although not always) black, with a fine purple or violet gloss. The habits, &c. of a French species, the X. violacea, have been carefully studied. The females of this species appear in the spring, and select posts, palings, &c., in which they construct burrows from 12 to 15 inches in length, and rather more than half an inch in diameter. The two extremities of the tunnel are covered, leaving a narrow passage at each end. Upon the completion of these works, they deposit an egg at the bottom, with a due supply of pollen-paste; the whole is then covered with a layer of agglutinated sawdust, formed during the construction of the burrow. The layer thus formed is made to act in the double capacity of a roof for the original cell and a floor for another above it. In this manner about 12 cells are usually formed. When the larvae are full grown, they assume the pupal state, head downwards, so as to allow the lowermost and oldest to make its way out of the bottom of the burrow as soon as its wings are sufficiently developed, and which consequently occurs sooner than in those in the upper cells.

The males of some of the large species, X. latipes and others not yet properly described, have the fore-legs greatly dilated. An excellent history of the Xylocopa is given by Réaumur (Mém., tom. vi., mém. iv.).

XYLOIDINE. This name has been given to paper which has been immersed for a moment in strong nitric acid, and then washed in distilled water. The paper assumes the feel and toughness of parchment, and is so combustible as to serve for tinder.

XYLOMA, a genus of fungid plants approaching in character to that of Spharia. From this genus it was formerly distinguished by negative characters, such as the cavity not being external. All the species which were referred to this genus are placed by Berkeley under the genera Spharia, Hysterium, Phaeodium, &c. The most common species of this genus are found on the decaying leaves of trees, especially of the sycamore and maple, the lower of which are frequently covered with black spots, as the results of the attacks of fungi formerly referred to this genus.

XYLOMELUM (that is, 'wood-apple'), a genus of plants belonging to the natural order Proteaceae. The Proteaceae are placed by Lindley in his tubifserous group of incomplete Exogens. The type of this order is Protea, which was so named on account of the variable forms of foliage prevailing amongst its species. Nor has the subsequent discovery of numerous genera and species rendered this name at all inappropriate for the whole family. Our knowledge of these plants is entirely of a recent date, only the species of the genera Protea and Leucodendron being known to Linnaeus. Jussieu was the first who established this order, in his Genera Plantarum; and his definition of it applies to nearly all the species and genera since added, but it is to Brown that we are more indebted for our knowledge of this order than to any other writer.

The order Proteaceae possess the following characters: the perianth or calyx is 4-leaved; the sepals distinct, or cohering into a tube with a 4-cleft limb; the sepals subcoriaceous, coloured, pubescent externally, and valvate in vaccination; the stamens definite, opposite the lobes of the calyx, and generally exerted with very short filaments; the pollen is normally triangular, sometimes elliptic or cuneate, rarely spherical; occasionally there exist four hypogynous scales or glands, or barren stamens, alternating with the lobes of the calyx and prefiguring a corolla; the germen is free, often stipulate, formed of a single carpel, the style simple and terminal, and the ovules 1, 2, or many; the fruit is variable, either dry or succulent, and either deciduous or indefinite; 1, or more seeds; the seeds without albumen, often winged, and furnished with a clipeus; the embryo straight and white, with two or more cotyledons, the plumule scarcely visible, and the radicle inferior and short.

The species are shrubs or small trees, with usually um-
This order is very easily distinguished by the hard, dry, woody texture of the leaves, by the irregular perianths having a valvate evagination, the stamens placed on the lobes of the perianth, and by its dehiscent fruit. Another characteristic of this order is distinguished from others which are allied to it is that the radicle points towards the base of the fruit. In this order there is one herbaceous plant, the *Symphionema posticum*. Pubescence is very general, and consists either of a short impalpable tomentum of soft hairs. The existence of or absence of this pubescence in the leaves cannot always be relied on in distinguishing the species, but the short tomentum of the under surface is of greater consequence than the spreading hairs. In the bractes and flowers more dependence may be placed on it. The external envelope of this order is coloured, and has the external characters of a corolla; but Brown has, with Jussieu and Adanson, denominated this a calyx, 'chiefly because the staminodia, of equal number with its lamina, are constantly opposite to them, and from the close analogy subsisting between this family and that of Thyme and, in which, I believe, the greater number of botanists will allow that this envelope is really calyx.' (Brown.) One of the most remarkable points in the calyx is its invaginate division into four leaves or segments, although it has a strong tendency to irregularity. In the distinction of the genus the stamens afford good characters. The deviations from the usual structure of the anthers are not many, but are singular. In the genera *Simia*, *Conospermum*, and *Symphionema*, they are syngenesious, and not only do the anthers adhere together, but the corresponding lobes of these being, when considered separately, entirely open, are so applied to each other as to form but one cell without a trace of any intermediate trace. The peculiar structure of the genus *Helwindia*, named after the Hon. D. R. Bellenden Ker, who has published many valuable papers on botany in the 'Annals of Botany' and the 'Botanical Magazine.' *Grevillea* was named by Brown in honour of Sir Joseph Banks, his intimate and constant friend. *Unilocular*, a genus closely allied to the former, was named in honour of Mr. Dryandra, a learned botanist and a distinguished patron of the scientific arts. *Knightia* is a genus which was discovered by Joseph Banks, and, at his suggestion, named by Brown in honour of the late Honourable Charles Francis Greville, a most natural history, and for many years an editor of the *Botanical Magazine*. *Dryandra* was named by Sir Joseph Banks, who was associated with the late Dr. Banks in the examination of the specimens of vegetable products of the South Island. *Dryandra* was named by Sir Joseph Banks, a genus closely allied to *Bankia* and equalled in number, habits, and the botanical sciences.

The geographical distribution of these plants is interesting. They are almost entirely confined to the southern hemisphere, an observation first made by Mr. Banks. Their diffusion is very extensive in this hemisphere, being confined in latitude and longitude in its eastern limit. They cover not only the larger southern continents but are also found in New Zealand and New Caledonia. They have not hitherto been found in Madagascar or lesser islands of the South Seas. In America they have been found in Terra del Fuego, in Chili, in Peru and Guiana. The American species have more affinity to those of New Holland than of Africa. It may be inferred that this family of plants is distributed over Africa, which are abundant at the Cape of Good Hope, and Blue is a genuine species of Protea in Abyssinia. Western shores of New Holland have been explored, an account of Proteaceous plants have been found, the great new the order existing here in about the same latitude as the Cape of Good Hope. One of the most remarkable species is that of *Dryandra*, a genus closely allied to *Bankia*, and equalled in number, habits, and the botanical sciences.
from the structure of the order, are the most local, and are found either in the principal parallel or in the highest latitude. The range of the species of the order is very limited, and there has been no instance recorded of a species of this family being found in the eastern and western shores of New Holland. Baskets and told it is probably the most widely extended species; but although its range of latitude is very considerable, its extension in longitude is very small.

'The favourite station,' says Brown, 'of Proteaceae is in dry, stony, exposed places, especially near the shores, where they occur also, though more rarely, in loose sand. Scarcely any of them require shelter, and none a good soil. They are found in wet bogs or even in shallow pools of fresh water, and at the height and nakedness of the Alps in the savannahs, grows, according to him, in salt marshes. Respecting the height to which plants of this order ascend, a few facts are already known. The authors of the "Flora Peruensis" mention in general terms several species as being alpine; and Humboldt, in his valuable chart of equinoctial botany, has given the mean height of Embothrium emarginatum about 9300 feet, assigning it a range of only 300 feet. 'On the summits of the mountains the tips of plants may be found, the genus, less, in the common height of about 4000 feet, I have found species of Embothrium, as well as other genera hitherto observed in no similar situation. Embothrium however, as it is the most southern genus of any extent, so it is also, as might have been expected, and thwart for the principal, and in the genus only of this order are found in more than one continent. Rhopala, the most northern genus, which, though chiefly occurring in America, is to be met with also in Japam-China and in the Malay Archipelago; and Embothrion genus most of any extent, is common to New Holland and America.'

None of the plants belonging to the natural order Proteaceae are remarkable for their medicinal properties. The fruit of a species of the genus Guepinia is said to be sold in the markets of Chili under the name of Jaltas. In the Cape of Good Hope the plants of this order are most frequently made use of as fire-wood. For this purpose the dry woody character of their leaves peculiarly fits them. The seeds are frequently used by gardeners who appear to be much prized by gardeners, and form a part of every good collection of plants. One of the finest collections of these plants in this country is at the Royal Gardens at Kew, where a great variety of this singular and interesting order is represented. A genus, less, in the neighbourhood in this country are Grevillea, Banksia, and Dyandra. The fruit of the Xylometum pyriforme, which the cut accompanying this article represents, is very hard, and is known in New Holland under the name of Wooden Pear. It is supposed to grow in Natal, from which several very hard seeds, which must come from their places of growth, the seeds should be sown in pots filled with a sandy loam, and placed in a hotbed: when the plants come up, they should be carefully given them. Some of the species may be propagated by cuttings, which should be planted in the spring or summer, and placed in a hotbed. These plants should not have much water, nor be treated very tenderly. (Brown, 'On the Proteaceae of Jussieu,' in vol. x. of Pl. Tract.; Jussieu, art. 'Proteaceae,' in Dictionnaire des Sciences Naturelles; Burnett's Outlines of Botany; Lindley, Natural System.)

XYLOPHAGA. [PHOLAS, p. 108.] XYLOPHAGI (that is, wood-eaters), a family of insects of the order Homoptera, which are divided from the family which usually precedes them (the Weevils) by the absence of a proboscis. The antennae are thickened towards their extremities, or perforated from the base; always short, and usually composed of less than fifteen joints. The palpi are small, and do not exceed the first three joints. The insects generally live in wood, which is perforated and channelled in various directions by their larvae. Some species are destructive to pines and firs, some to olives, while others feed on fungi. This family is divided into three sections.

Section I.

Those which have the antennae composed of ten joints at least, either terminated in a thick club, generally solid, or having three elongated plates, or forming a cylindrical and perforate club from the base; the palpi are conical; the anterior tibiae in the majority are toothed and armed with a strong hook, and the tarso generally have the penultimate joint of the palpi very short, and the antenna terminated in a solid or trilaminar mass, preceded by five joints at the least.

These Xylophagi compose the genus

Scolytus. Geoffroy.

In some the penultimate tarsal joint is bilobed, and the antennae have seven or eight joints preceding the club. Scolytus proper (Receptogaster, Herbst) has the antennae composed of ten or eleven joints before the club, the palpi are subconical; the anterior tibiae of the majority are toothed and armed with a strong hook, and the tarsal joints generally have the penultimate joint of the palpi very short, and the antennae terminated in a solid or trilaminar mass, preceded by five joints at the least.
Fossil specimens of this genus have been found embedded in amber.

The others have the palpi large, very visible, and of unequal length; body depressed and narrowed anteriorly; the antennae either 2-jointed (the second joint being very large and irregularly shaped) or 10-jointed and entirely perforated; tarsi entire.

These insects are of great rarity and very singular appearance, and are also foreign to Europe. They compose the genus

*Paussus.* Linn.

*Paussus* proper has only two joints to the antennae, the second very large and compressed.

*Paussus* succinctus. Professor Azellus observed a dim phosphoric light to be emitted from the singular holow antennae of this insect. (Linn. Trans., iv. 201.)

*Hylotornes,* Dalm., composed of a single species, apparently with ocelli, and with the antennae scarcely longer than the head, 2-jointed.

*Cerapterus,* Swed., has the antennae 10-jointed and perforated. (See Westwood's Monograph upon the genus *Paussus,* in Trans. Linn. Soc.)

Section II

Those which have only 10-jointed antennae, and the maxillary palpi do not taper to a point, but are either of equal thickness throughout or dilated at the extremity.

The joints of the tarsi always entire.

They are divisible into two principal genera, according to the mode in which the antennae terminate. The three terminal joints form a perforate club in the first, or

*Bostrichus.* Geoffr.

*Bostrichus* proper has the body more or less cylindrical; the head rounded, nearly globular, and capable of being rounded into the thorax as far as the eyes; the thorax is never less convex before, and forms a kind of hood. The two first joints of the tarsi, as well as the last, are elongated.

The species is found in old wood and timber.

*Bechnoter* dispars, Fabr., *Hylotornes dispars,* Erichson.

This *Apple-Bark Beetle* is very common in Austria, but rare in this country. It is termed *dispars* because the male is not only about half the size of, but differently formed from, the female, bearing more resemblance to *Anoplognathus* than to the *Bark-beetles* generally.

The head and thorax are black; the extremity of the palpi and antennae reddish; the wing-cases long, blackish, and somewhat hairy; the feet dilated, and of a reddish yellow; the tights black. The female somewhat resembles the *Longhorn-Bark-Beelee, Bostrichus rufipes,* but the wing-cases are not deeply furrowed, and the spots not so deep as they are in that species. The male (as we have previously observed) is smaller than the female, and it has chestnut-brown wing-cases and reddish tights. These insects, in their attacks alone, are entirely to the detriment of the tree. They make no distinction between the age or healthy state of the tree, whether it is young or old, or whether it may shoot out much or little; all that they require is that it shall not be of less thickness than about half an inch in diameter. Having found a tree suitable, the females bore a completely round but somewhat oblique hole, penetrating nearly to the centre of the tree: she first goes upwards to the side, and then downwards. Upon coming near to the bark, she turns back, and goes to the other side downwards, forming a new path. These paths, leading upwards and downwards, seldom exceed one inch and a half in the minute particles of wood, or worm-meal, which are ejected, indicate the presence of the insect. In case of the pine beetle, *Bostrichus graphus* and *piniperda,* it is stated by Bechstein to be ejected by the larva, but in this case it is thrown out by the beetle itself. We give the following extract from Köll's work 'On Insects injurious to Fruit-Trees,' &c., bearing on these particulars, and, if correct, the insect should be at variance with the recorded habits of the family:—

> At the end of the entrance the female makes a somewhat wide apartment, and lays her eggs in it in a heap: they are of a snow-white, longish, and of a somewhat posteriorly pointed form, from seven to ten in number, and sometimes fewer. The path however is previously pretty thickly covered with a whitish substance, which resembles an incrustation of salt. I consider this as a kind of ambrosia on which the hatched larve feed; and I conclude it is their principal nourishment, as I saw no passage or chamber in which the eggs were laid without this substance, and no full-grown larve in the passages and chambers in which this substance was not consumed. As has been used it is whitish, easily rubbed with the finger to the touch, powdery, melts on the tongue, and is without any palatable taste. I am of opinion that the female forms this substance from the sap of the tree, to which she adds a peculiar juice.

*Bostrichus typographicus,* the Typographer or Beetle, is perhaps the most destructive of the whole class. It particularly attacks the silver-firs (*Picea pascense*), but when that tree is not abundant, it will attack itself other species of pines and firs. The perfect beetle is the two to two and a half lines long, and from one to one and a quarter to a quarter of an inch broad, and has a black and white striped body. As it ramifies into the bark, it is of rusty yellow; but on exposure to the changes to a brownish black colour.

The injury this insect does is chiefly effected by the larve, which destroy the sap-wood; and, then, if the numerous, can kill a healthy fir in the course of a few weeks.

This beetle committed immense devastation in the north of Germany about the close of the last century.

*Bostrichus orthographicus,* Duftsch., or the Spruce-Bark Beetle; *B. laricis,* Fabr., or the Larch-Bark Beetle; *B. Pinaster,* Bechst., or Red Bark-Beetle, require no particular notice.

*Pico,* Fabr., has the body narrower than *Bostrichus* in the thorax, and the antennae flat.

*Cis,* Latr., has the body oval, depressed, and bevelled; last tarsal joint much longer than the first head of the males frequently horned. Many minute species are found on fungi.

*Nasutus,* Desmar., has the body long, linear, and mandibles robust and exsured. *N. elongata* is a rare and rare British species, sometimes found under the bark of old paling.

The second genus is distinguished from the first having the club or tenth joint of the antennae solid and button-shaped; the body is elongated, with the head narrowed into an oblong snout or muzzle; the palpi are very small, and as well as the mandibles, divisible into two joints.

This genus is termed

**Monotoma.**

*Monotoma* proper, Herbst, has the head as large as the thorax, and separated from it by a narrower part.

*Cecidomyia,* Lain., has the front of the head produced at an obtuse triangle, the first joint of the antennae longer than the second; the body nearly oval or paripiped, and the elytra not truncate behind.

The genera *Synchita,* Heuw., *Rhizophagus,* Herbst, are included in *Monotoma,* but are not deserving of a special remarks.

Section III

The *Xylaphagi* of this division have eleven distinct in the antennae; the palpi filiform, or thickened at the tips and at the angles, and not perforate; the last joints entire. Those in which the club of the antennae consists only of two joints constitute the genus

*Lytus.*

*Lytus* proper, Fabr., has the mandibles and basal joint of the antennae exposed. *Diodesema,* Megerle, and *Bo.* Herbst, are included in the genus *Lytus.*

In some of the mandibles are concealed or scarcely visible.

These are the genus

*Mycetophagus.*

*Mycetophagus* proper has the antennae at least as long as the thorax; body oval; thorax transverse; and club of the antennae commencing at the sixth or seventh joint.

*Scolanus* has the body nearly linear, of greater length than breadth, and as broad as the base of the elytra; *S. dentatus,* a small flat insect, frequent floating found floating in tea and coffee, being introduced with sugar. In others the mandibles are entirely exposed large; the body oval and broad, and the elytra not truncate behind. These insects constitute the genus

*Trogosia.* Olivier.

*Trogosia* proper has the antennae shorter than the thorax; the mandibles shorter than the head, and convex to the labium; the antennae all at the ends between the palpi, and the maxillae have a single joint.
The reader who has carefully followed us over the three sections of the Xylophagine will readily perceive that Latin is a language in which the use of the genitive is a transition between the Cercidionae and Cerambycidae, commencing with those which have the club of the antenna solid, and proceeding through those families in which the club is less compactly constructed, as far as the Trogositalae. In this transition the number of the points by which the antennæ are united becomes entirely obvious enough; but in other and more important points, as for instance in the structure of the imago, as well as in that of the larva, it cannot be maintained; and in the section of the Trogositae, to the Nitidulidae, and in the Eudocinidae, the number of the points of union becomes still more obvious. But the number of these points in the Nitidulidae, and in the Eudocinidae, is not as yet sufficiently determined, and it is not possible to determine it in these families with certainty. The number of the points of union in the Trogositalae is, however, determined, and it is equal to three.

The genus Scarabaeus, Linn., comprising two divisions, corresponding with the families Dynastidae and Rutelidae of MacLeay,

The Dynastidae (comprising the Gastrotrapes of Fabricius) constitute an extensive series of gigantic insects, the males of which are pre-eminentiy distinguished by various peculiar protuberances, horns, or tubercles arising from the thorax and horns, and often from both these parts (occasionally arising from a very peculiar appearance) and of which the females are destitute. The cephalus is small, triangular, pointed in front, or terminated by two small obtuse teeth; the labrum is a broad membranous plate, furnished with two or more oblong teeth; the tibiae are very robust and horned, furnished with one or two obtuse teeth. The maxillae are either terminated by a coriaceous ciliated lobe, or by an elongated cornaceous piece, having one or several acute teeth on its sides; the mandibles are furnished with an ovoid or triangular form, truncated in front; the prosternum is not produced behind into a lobe; the tarsal claws are of an equal size, and the scutellum is distinct; the elytra do not entirely cover the extremity of the abdomen; the antennae are not furnished with a club, and the lamellae are not being enclosed within the two external ones.

The colour of these insects is usually of a dark rich brown or chestnut colour. They reside either in rich vegetable mould or in the putrid detritus arising from the decay of vegetable tissues.

Oryctes, Illiger, is a very numerous genus, having the legs all nearly of the same length, with the four hind tibias thick and crooked. As a type of this genus, we may take the common continental species, O. natesornis, which is frequently collected. This insect is about the size of a grain of hempseed, and of a yellow colour; the larva continues in that state four or five years, and then encloses itself in an oval and very smooth cocoon; the pupa lies upon its back, and the adult imago remains in its cell for about a month after it has attained the perfect state. The insect is about one inch and a half long, and the male is distinguished by having a curved horn upon the head.

Some of the Dynastidae require an immense size. The Scarabaeus hercules, Linn., an inhabitant of South America, is five inches long.

The Rutelidae chiefly occupy the tropical zone, there being only six or eight species found in Europe.

Xylophila, Linn., is a species of the Rutelidae, with which we may often fancifully attempt to extend the species of this family, from which they differ in the absence of the peculiar horns or prominences which are present on the heads of the males of the Dynastidae. The antennæ are 10-jointed, the club 5-jointed; the labrum is externally furnished with two paired external protuberances, and within; the mandibles are short and corneous, and more or less exserted with a notch on the outer margin near the tip; the maxillæ are also horned and truncate, and with four or six strong teeth at the tip, with the labium sometimes membranous; the labium is externally furnished with the mentum; the elytra do not conceal the extremity of the abdomen; the thorax is transverse-quadrate; the scutellum large and distinct; the mesosternum is anteriorly produced between the middle legs, the legs are robust, with the posterior femora sometimes greatly thickened; the claws of the tarsi are generally unequal in size, and occasionally divided; the elytra commonly exhibit a transverse section, dividing as it were into two parts before the eyes. (Westwood.) The head and thorax are identical in both sexes.

For a few exceptions, the Rutelidae are confined to the equatorial regions of America.

Xylophilus, Linn., is a genus of plants belonging to the natural order Euboeiacae. The species of this genus are shrubs, with a hard and rigid foliage. The flowers are monocious. The male flowers have a calyx cut into six segments, three of which are thick and fleshy, and a nectary composed of six glandular globules. The calyx and nectary of the female flowers are the same as the male; the styles are three; the stigma is 3-cleft; the fruit is a 3-celled capsule with six valves, and two seeds in each cell.

This genus closely resembles Phyllanthus. Most of the species are natives of the West Indies, where they are known by the name of sea-side laurels and love-flowers. They vary principally in the form and character of their leaves, and their specific characters are chiefly founded on this character. These plants have many of them been cultivated in the stoves in European collections. They may be propagated by seeds or by cuttings, and always acquire a stem of the highest order. They require the constant protection of the stoves in winter, but in the hot summer months they may be exposed to the open air if taken in on cold nights.

Xylopia, Linn., is a genus of plants belonging to the natural order Annonaceae. It has a 3-jointed calyx, with ovate coriaceous acutish segments; 6 petals, of which the 3 outer ones are largest; numerous stamens inserted into a globose receptacle: from 2 to 15 carpels on short stipes, flattened, 1-celled, 1-2-seeded, sometimes dissected, some segments renate; the seeds are covered with an aril. About twelve species of this genus have been described, all of them natives of South America. They are trees or shrubs, with oblong or lanceolate leaves, and axillary, bracteate, 1- or many-flowered inflorescences, the woody at all times is bitter. The botanical names of these are called Bitter-trees.

X. fruits, Shrubby Bitter-wood, is a native of Brazil and Guiana. It is a shrub about 6 feet in height, and has oblong-lanceolate acuminate leaves, with the under surface silky, the peduncles very short, and the carpels smooth. The bark of this plant is manufactured into cordage. The leaves and wood are aromatic. The seeds also contain an acid aromatic oil, and are used in Guiana by the negroes as a substitute for pepper.

X. glabra, Smooth-leaved Bitter-wood, is a native of the islands of Barbadoes and Jamaica. It has oblong-obovate smooth leaves, with 1-flowered peduncles, solitary or in pairs, and smooth carpels. This plant is a tree, and attains a height of 40 feet. The wood, bark, and berries have an aromatic bitter taste, and are used by the Carib Indians. Pigeons feed on the berries, and the flesh of these birds is improved in flavour during the season they eat them. When fresh gathered from the tree, the berries have an agreeable flavour, and are eaten as a fruit. When dry, the outer skin or pericarp is greatly reduced. Sugar sent to this country in hogsheads made of it could not be prepared. Articles of furniture made of it are proverbial for the attacks of insects; the wood is very soft, and the carpels have a bitter taste which it produces in their moulds from the dust.

X. sericea, Silky Bitter-wood, is a native of Brazil. The woods of Rio Janeiro. It is a tree about 20 feet high.

The branches are clothed with a rustulous down, the leaves are lanceolate-oblong, with long points.
The Xyris group of Endemic.

The species are herbaceous plants with fibrous roots. The leaves are radical, sword-shaped, scarious, dilated and equitant at the base. The flowers are arranged in terminal naked imbricated heads. The calyx is glumaceous, 3-lobed; the corolla petaloid, coloured with three petals; the stamens 3; the flower inserted upon the claws of the petals; 3 sterile, alternate with the petals; the anthers 2-celled, and turned outwards; the ovary single, the style bifid; the stigma multifid or undivided; the capsule 1-celled, 3-valved, many-seeded, with a petal placenta; the seed with the radicle on the outside of the albumen, and at the end most remote from the hilum.

This order is united with Restiaceae by Brown and other botanists. The species are found generally in the hotter parts of the world, chiefly in the tropics of America, Asia, and Africa. Some of the species of Xyris are found in the southern states of North America. Of their properties very little is known. X. indicus is said by Agardh to be used as a remedy in itch and leprosy.
Y.

Y has found its way into the alphabets of Western Europe through the later Latin alphabet from the Greek. The oldest form of the Greek character appears to have had no vertical stroke, but to have been precisely the same as the English or Roman V, so that the small character v differs from the small Greek v only in the incline of the curve for an angle. We have said that the letter Y belonged only to the later Roman alphabet. This fact has been already remarked upon under X; and an argument in confirmation of what is there asserted may be drawn from the occurrence of the character between the sounds of name and u in their V the representative of the Greek letter. How then, it may be asked, was it that they subsequently adopted this letter? The answer should probably be this — that the Greek character had changed its power from the original sound of oo, such as is still represented by the Italian u, to a sound probably like that of the French u, or even to a weak i. If we traced the Greek letter Y or V still farther back, we should perhaps arrive at the opinion that it grew itself out of a careless omission of O. The Hebrew character which corresponds to O, viz. Y, already exhibits the opening above, just as the Hebrew W does, compared with the Greek θ. So too the English often write a capital O without joining the circle at the top. To these conceptions, Charles II. was born in the character Y, which ended with a T, contains no other equivalent for the Greek Y; and again the Etruscans had but one character, V, without any O. That the introduction of the character Y into Latin words has been carried beyond the bounds of a mere epigraphic (X), and that any such word would add to what there has been said, that in the well-known Medicean MS. of Virgil there is something suspicious in the fact that this letter always overtops the other letters in such a manner that the vertical shaft is of greater height than that of the hones, if we may so call them, were attached by a subsequent hand, the manuscript until then having merely an (See Foggini's reprint of that MS, and the second line of the copperplate facsimile of the same (anaisiara) of an old Virgil, vol. i., facing p. xxxvi. of the face.)

In the English language there is a great tendency to use his letter at the end of words. This has probably arisen from our having of a tail to the last unit of the tonumalns, preferring ti, ti, vi, &c.; so that to please the eye and give a sort of finish to a word, say, boy, hery, were preferred to nei, be, thei. Before we leave the form of the letter, it may be observed that in y, y', for which it has been supposed by many, that y was the intermediate there of John Youlind, gentleman, who was page, &c., as in Wood: he is stated to have died 25th July, 1670, in his 59th year. Thomas Yalden, or Youlind, was admitted of Magdalen College, Oxford, in 1690: and was, with a brother, employed in the composition of Namur, a Pindaric Ode inscribed to his most sacred and victorious Majesty. He had taken his degree of M.A. with great applause in 1694, and having then entered into holy orders, he succeeded Atterbury, in 1694, as lecturer at Bridewell Hospital. In 1700 he published a poem entitled 'The Temple of Fame,' on the death of the duke of Gloucester, and was the same year made fellow of his college. Soon after this he was presented by the college to a living in Warwickshire, which he held, along with his fellowship, and he was also elected moral philosophy reader, 'an office,' says the 'Biographia Britannica,' 'for life, endowed with a handsome stipend and peculiar privileges.' On the accession of Queen Anne, he wrote another poem, in celebration of that event; and from this time he is said to have unreverently sung through the whole church party. In 1706 he was taken into the family of the duke of Buckingham, and the following year he took his degree of D.D. Some time after this he was presented to the adjoining rectories of Chalton and Cleeve and in Hertfordshire, and he is said to have also enjoyed the sincere prebends of Deans, Harris, and Pendles, in Devonshire. Upon the discovery of what is called Bishop Atterbury's plot, in 1722, Yalden was taken up, and his papers were seized; but it soon appeared that although he was intimate with Kelly, the bishop's secretary, and in the habit of corresponding with him, the treason, if it existed, was certainly in no part of his concoction. All that is known of him is, that he died on the 16th of July, 1736, having to the end of his life, as Dr. Johnson expresses it, 'retained the friendship and frequented the conversation of a very numerous and select set of acquaintance,' and that poems that have been mentione
d
Carbery Price, a poet; 'A Hymn to Darkness,' in imitation or emulation of Cowley, which Johnson considers to be his best performance, and to be 'imagined with great vigour, and expressed with great propriety.' "A Hymn to Light," which, in the estimation of the same authority, 'is not equal to the other;' a translation of the second book of Ovid's 'Art of Love,' and many other translations and short original pieces. Many of Yalden's productions in verse are scattered through the third and fourth volumes of Den's (or Tonson's) collection of 'Miscellany Poems;' a number of them are also given in the more recent collections of the English Poets, by Johnson and A. Chalmers; but some appear to be lost, or at least they eluded the researches of J. Nichols (see his Bibliography, iii. 167, and iv. 198). Yalden, who had considerable humour, is the author of a paper in prose, entitled 'Squire Bickerstaff Detected, or, the Astrological Impostor Convicted;' it is a pretended answer to Swift's attacks on Partridge, the astrolagor, who drew up on Partridge's application, and which that person is said to have printed and published without any presumption of the joke. It is printed in most of the editions of Swift's Works.

YALLOFFS. [YALLOFFS.]

YAMA, or YAMA-MUNA, or JUMNA. [HINDUSTAN, p. 215.]

YANG-TSE-KIANG is the name by which one of the largest rivers of Asia is generally known in Europe. It drains the north-eastern districts of Tibet and the central provinces of Mongolia proper. The Yen-ch'i of Pekin is the interior of Asia, about 1850 miles from its mouth in a straight line; but as the river frequently changes its direction and makes very large bends, its whole course is computed to amount to 2000 miles, and it probably exceeds 3000. In length it may therefore be compared with the Amazonas (3300 miles) and the Mississippi (3200 miles). The country watered by the Yang-tse-kiang and its numerous tributaries is estimated by Ritter to have an area of 300,000 square miles, and is equal to the surface of all the countries of continental Europe, as far east as a line drawn from the northernmost corner of the Adriatic northward to the mouth of the Oder in the Baltic.

Upper Course.—The head-waters of this river have never been visited by Europeans, and from not having been known in China until the emperor Kanghi sent persons to ascertain them, and wrote a short memoir on them, which has been translated by Klaproth, in his 'Memoires relatives à l'Asie.' According to the statements in that memoir, the Yang-tse-kiang rises between 32° and 90° north, and between 4° and 35° N. lat., in the Bayan Khara mountains, one of the principal ranges of the Kuenlun system in three branches, all of which bear the Mongol name of Oolun muren; but to the most northern the name of Oolun is prefixed; that of the middle is designated as Toktonai, and the southern river is called K'ai-si. These three rivers run from west to east. The Kat'ai-o olan-muren is joined from the south by a small river bearing the name of Mirus-usu, and from this point, the river flows northward about 180 miles, and then turns to the east, in which direction it runs about 100 miles, where it is joined from the north by the Min-kiang or Tchou and from this place the name of Kin-chia mother of the Tung-tsekiang, or great river). The Kiang runs in a north-eastern direction about 360 miles, where it passes north of 39° N. lat., and then its course is directed to the east by some offsets of the mountain-ranges and forms numerous waterfalls and eddies; then it is more or less divided, and having been floated down the immense rifts of timber where it is found in the middle parts of the course floating far from the provinces near the Pacific, so that the supplies of such water must be derived from an immense country covered with snow, and such a country is only found on the upper part of the course.

Middle Course.—The middle course of the river is through a hilly country, and extends from Tung-Chafoo to King-tseh-foo, at which place it enters the narrow valley of the Tung-tsekiang and flows northward about 180 miles, and then turns to the east, in which direction it runs about 100 miles, where it is joined from the north by the Min-kiang or Tchou and from this place the name of Kiang-chia, from which the Kiang, our large river, takes its name. The Kiang runs in a north-eastern direction about 360 miles, where it passes north of 39° N. lat., and then its course is directed to the east by some offsets of the mountain-ranges and forms numerous waterfalls and eddies; then it is more or less divided, and having been floated down the immense rifts of timber where it is found in the middle parts of the course floating far from the provinces near the Pacific, so that the supplies of such water must be derived from an immense country covered with snow, and such a country is only found on the upper part of the course.
extent of the rafts of timber which he daily met with on the Kiang. They were only ten feet wide, and of different lengths, the longest about a mile or a half in length: but their number was so great, that if all of them had been put together, they would have covered a space of several days' journey. At some places they were fastened to the banks of the river, and it took him more than an hour, or even half a day to pass them. These rafts rose about four or five feet above the surface of the water, and consisted of several kinds of wood. On the rafts were placed other articles, among which he mentioned drugs, parrots, and monkeys: but it appears that rhubarb, musk, and chirwory, which are very far from being the most lucrative articles of trade, were going to Peking. The hilly country, through which this part of the Great River lies, improves lower down. The country near the mouth of the Ta-kiang is mostly covered with high hills, which at some distance rise into mountains, which are not capable of cultivation, but are covered with extensive forests, consisting of different kinds of pine, fir, cedar, and juniper, and a part is overgrown with bamboo. The remainder is well cultivated, and the fields are studded with large plantations of fruit-trees, among which oranges, lemons, and citrus are mentioned. Such is the country near Sui-te-hou, a large commercial town at the mouth of the lesser Ta-kiang. At the mouth of the Kiang-ling, which joins the river farther down, and which is the only branch from the Yang-tse-kiang, that lies the town of Ta-hung-kiang, one of the most important on the banks of the river. In these parts the mountains do not rise to such an elevation as farther up, and the greater portion of the country is under cultivation, and has extensive banks and islands in abundance. Cultivation increases lower down the river to the still more important town of Kuie-she-hou, which stands on the northern banks of the Ta-kiang, in one of the richest parts of China, where hardly a spot is to be found where a crop cannot be raised. This river has become so important a product of the place, that the exception of the coast of the Tap-lung river, which lies about 35 or 40 miles distant from the town, and inhabited by some mountaineers. But this range supplies the town with coal, and vast quantities of salt, which is sent from Kuie-sheh-foo to the lower courses of the river. The Lower Course of the river is 820 miles. From Kiang-te-hoou the river runs about 100 miles south-east, past the outlet of Lake Tung-ting, from that place north-east to the place called Yumichiti or Tappa-ling, from thence to the upper reaches of the river. The Peking tributaries of the river, which empty into the Great River, are numerous and extensive. The rivers, tributaries, and lakes are so distributed as to be easily managed by art, and hardly ever leave the contiguous country, as is repeatedly the case in some regions adjacent to the Hoangho. This plain may be about 200 miles from west to east and about as much from north to south, and is called Yumichiti. Nearly all the productions of China are here raised in the greatest abundance; no spot is uncultivated, and towns and villages cover the country on all sides, and several large towns are found on the banks of the Ta-kiang, as this river and its tributaries supply more extensive and easy means of water-communication enjoyed by any other part of China, except the country immediately adjacent to the Great Canal. Besides several smaller rivers, the Kiang receives from the south a great volume of water by the channel which, issuing at the north-east coast of Lake Tung-ting, flows through the country between 130° E. long. This lake is of great extent, being, according to the statement of the missionaries, more than 200 miles long. It is surrounded by an extremely fertile country, which even in the driest seasons yields abundant crops, the means of irrigation derived from the lake never failing. Two large rivers, originating on the northern declivity of the Nan-ling Mountains, and draining a country as extensive as the island of Great Britain, fall into this lake, the Tsing-shui-kiang and the Hoang-hing, each running more than 400 miles. We have no account of the country drained by these large affluent of the Kiang, nor of the rivers themselves, but we know that there are large towns on their banks at a great distance from their mouths. The largest of these are Ta-kiang, which rises on the southern declivities of the Peking, drains the wide and fertile valley enclosed by the Pe-ling and Tapa-lang ranges, runs nearly parallel with the Ta-kiang, and falls into it after a course of about 500 miles, a great number of towns on its banks, and the river seems navigable nearly to its source. By means of the easy water-communication afforded by these rivers and several large lakes, the country contiguous to the banks of this portion of the river is the most cultivated of any part of China. The drainage of an immense area, and the towns built on them are very populous and industrious. Kiang-te-hou-foo, situated where the river enters the plain of Yumichiti, is large, rich, and well fortified. Where the Han-kiang joins the Ta-kiang there are two large towns, the Tung-ho-foo and the southern Shores. The last-mentioned place is compared by the Jesuits to Paris in extent, and the first to the second town of France. The navigation in the neighbourhood of these two places is so active, that from 4000 to 5000 river barges, some equal in size to the coasting vessels of France, may always be seen either at anchor or plying between the two towns. About 30 miles farther down is the large commercial town of Hoang-te-hou-foo, surrounded by beautiful and fertile country.

The plain of Yumichiti is separated from Lake Poyang by a rocky country, which rises into low mountains, and comes close up to the banks of both the river and the western side of the lake. This mountain-tract is called the Yellow mountains. The lake extends nearly to the south, with an average width of 20 miles. It contains many islands, most of which are cultivated and populous. Both on the west and east it is enclosed by high hills where it approaches the Yang-kiang, but a large low plain surrounds its southern shores, and this plain is traversed by numerous arms of the river Kan-kiang, which is the largest of the rivers that fall into the lake. This river and the country surrounding it are better known in Europe than any other part of China. From Th Chow-foo to Canton to Peking, by which the embassy of Lord Amherst returned from the capital of China. The course of the river is about 300 miles in a straight line, but with its bends it probably exceeds 400 miles. It rises near the town of Chia-chou, and the great road leads to Canton, and becomes navigable at the foot of the pass, where the town of Nan-gan is built, though at this place its width does not exceed 10 yards. Small river barges ply between this place and Kan-kiang. As the river receives water by several tributaries which join it near this place. Hence it has sufficient water for large river-boats, but about 10 miles below the last-mentioned place are the Shepotan, or rocks with the eighteen cataracts. They are only rapids to be avoided in navigation. Barrow thinks that none of them are half so dangerous as the rapids were under old London Bridge at flood. The valley of the Kan-kiang up to the
of indifferent fertility, and comparatively thinly inhabited. Beyond them begins a wide, fertile, and very populous valley, which extends to the town of Nan-shang-foo, the capital of the province Kiangsi, which is large, well-built, and contains many edifices as large as palaces. Below this town the country extends in a low and level plain, which is traversed by the different arms into which the Kiang-kiang branches out before it enters the lake. No impediment to navigation occurs in the Kiang-kiang below the Shepotan. In the hills contiguous to the low plain of Lake Poyang, on the east, the best porcelain clay is found, and some of the largest manufactories of china-ware. It is only called shing (village), because it is not enclosed by walls.

After uniting with the channel which issues from Lake Poyang, the Yang-tse-kiang is always from 2 to 4 miles wide, and contains a great number of islands, most of which are low and formed by alluvium, but a few are rocky and elevated. The country on both sides consists of low hills, composed of sandstone or clay, which terminate on the river in steep declivities, and at some places in precipitous rocks. This country is of indifferent fertility, and a part of it is covered with forests, but is well cultivated. In the westerly part of this hilly country, a large and considerable basin, is the town of Ngaan-king-foo, or Gan-king-foo, a place of great commerce and manufacturing industry. The hilly country ceases where the river Tsahoo-kiang falls into the Yang-tse-kiang. This river brings to it the water of the large Lake Tsahoo, which the Yang-tse-kiang is joined, near the large town of Tailing-foo, by several small rivers. These, as well as the Tsahoo-kiang, are navigable to a considerable extent. From Tailing-foo the Yang-tse-kiang flows through a rather level country and between high banks, so as not to have a bottom along its bed. This country is of considerable fertility, and extends to the town of Nan-king, and even farther down to the vicinity of Tshing-kiang-foo, or the Great Canal.

About 46 miles below Nan-king the Yang-tse-kiang is joined on the north by the western branch of the Great Canal, and about 10 miles farther down, at the town of Kau-kiang-foo, by the eastern branch or principal branch. The Yang-tse-kiang has only been made to shorten the slow communication between Nan-king and the northern provinces, and the branches unite near the town of Yang-foo-teen-foo, one of the largest and most commercial towns in China, whose population is stated to be two millions by the English who resided there for a long time. Robert Hayner never thinks that the population of this place is overstated. From Yang-foo-teen-foo the canal runs directly northward along the borders of Lake Kao-yeou to the Hoang-ho, or Yellow, which is formed by the two branches just mentioned, and is the Great Canal, north of the Yang-tse-kiang, is the entrance to the southern portion of the Great Canal, at the town of Tshing-kiang-foo. This portion of the canal lies nearly parallel to the sea-shore, surrounds at some distance the Lake Taiho or Tai, and terminates at Hang-tse-kiang-foo, the capital of the Tsahoo-kiang. By these two canals the navigation of the Yang-tse-kiang is continued over the eastern and northern provinces of China Proper.

At the junction of the canals the width of the river is about two miles, but farther down it increases considerably. This part of the Yang-tse-kiang is very little known to us, as no European vessels have entered the river, nor have the Jesuits given any account of it. Even their maps is considerably different from Nelles's, in respect of the shallowness of the sea, but much less so in the interior of the country. It is however certain that even junks of the largest kind find no difficulty in sailing up the river to Tung-tshu-foo, a town on the northern side of the estuary of the Yang-tsekiang. Moreover, the mouth of the river seems to form an opening more than 60 miles wide.

In this opening, but much nearer to the southern shores than is the island of Tsang-ming, which is alluvial. It is supposed by Stantion that this island did not exist five hundred years ago, because it is not laid down in the oldest maps existing in Venice, where the Chusan Islands are entered, and that it has been formed since that time. The earthier matter brought down by the Yang-tsekiang was, as it is supposed, arrested at this place by the islands, and thus the island by degrees rose out of the sea. But the fact that the island is not destitute of fresh water, but, on the contrary, is traversed by numerous canals and dikes for the purpose of irrigation, seems to militate against this supposition. The island is about 60 miles long, and from 15 to 18 miles wide, and gives an area of about 900,000 square miles. The population is stated to be half a million, which is more than any tract in England of equal extent contains, except London and its immediate neighbourhood. The whole island is very fertile, and produces abundant crops. In some places salt is obtained, which, according to the missionaries, is extracted from a bed of earth, and is of excellent quality.

The depth of the Yang-tse-kiang, as far as up the tide ascends, that is, to Lake Poyang, is very great, and is expressed in the Chinese proverb, 'The sea has no bottom, and the Ta-kiang no bottom.' Such a depth is not found in any other river, except in the Amazonas, below the Straits of Olybys. These two large rivers are the only large rivers on the globe which open their wide mouths directly opposite the great tide-water, which rushes after rolling over a wide sea. Though the tides on it appears, does not rise more than from 6 to 8 feet. In one hour. The river Yarmouth is reckoned to be the greatest of these rivers, and of 400 miles from the sea in the Yang-kiang. In these two rivers alone several places are found where the same time the current flows the impulsive force received by the tide, and advances the current of the river. [Robinson's Travels, p. 27.] To this peculiarly may be ascribed the great depth of these rivers so far as the tide advances. The tide of course affects only the estuary of the river, and below it the natural current of the river; but the ocean, pressed to the bottom by the superincumbent tides, and thus confined, it scoops out a much deeper bed, so it does in other circumstances where such a pressure does not exist.

III.)

YANNINA. [Joannina.]

YAOORI. [Soudan.]

YARE. [Nauru.]

YARKIAN, or YARKAND. [Tian Shan Nt.]

YARMOUTH, or GREAT YARMOUTH, a borough, parliamentary borough, and municipal borough, county, county borough of Norfolk, and hundred of East Pakefield, in N.E. from London, by the road, 22° 36' N. lat. 1° 18' long.

Great Yarmouth is situated near the confines of the rivers Yare, Waveney, and Bure, which form a lake of the Brandy Water to the north-west of Yarmouth. The greater part of the town is on the east bank of the Yare; but it extends also along the east bank of the Bure, to Yarmouth, being contained within a boundary which included in the boundary of the municipal borough. The new bridge has just been commenced (November, 1850). The town is extending beyond the limits of the old walls, to the north towards Caister, and to the south towards Gorleston, a borough, which is a mile to the east of the old walls, between the old town and the sea. The village of Gorleston, to the south, near the mouth of the now connected with South Town.

The town of Great Yarmouth, within the boundary of the old walls, consists of three principal lines of streets, nearly parallel with the river, and of about 150 narrow lanes, or rows, which form the communications between the streets. The rows are extremely narrow, the length of the two rows being not more than eight feet wide, and impassable for ordinary wheel-carriages; the greater part of the traffic of the town is therefore carried on 'Yarmouth carts,' which are peculiarly constituted, low wheels, and adapted to the width of the rows: they are drawn by one horse, and look like sledges, but are red
ailled for conveying heavy goods. Some of the rows have been enlarged, particularly one near the middle of the town. There is an arcade of shops, and the principal streets are wide, and the houses are mostly well built, but the most substantial and handsome houses are situated along the quays. The provision-market is spacious; an open space near the town-hall is used for the weekly market, which is held on Wednesday and Saturday. The chief sales of corn are on Saturday. East of the town, next the sea, are a great number of houses, many of them large and some handsome, which are used as seaview mansions and summer seats.

Yarmouth as a bathing-place, certainly the best on the coast of Norfolk. The town beyond the walls consists chiefly of houses of the poorer classes, intermixed with warehouses, and is not paved, and only partly lighted by gas. It has 50 tons and three above 50 tons. The chief exports are fish, wood, and salt. South Town consists for the most part of good houses, but is only imperfectly paved and lighted, and Gorleston is neither paved nor lighted.

The river Yare, falling into the sea about two miles and a half south from Yarmouth, and the Bure, extending to the north from Braydon Water, form a kind of peninsula between the rivers and the German Ocean, near the centre of which the town of Yarmouth stands. The peninsula is low and formed of clay of some depth, and not more than 3 to 4 ft. in depth on the period Braydon Water was an open bay of the sea. The harbour is in the river Yare. There are no piers, South Pier and North Pier. South Pier is the larger; it is about a quarter of a mile long, well constructed, and previous to the Monthly Meeting the entrance of the river; but vessels drawing twelve feet of water, or about 200 tons burthen, can pass it at high water, and sail up to the town. The quay, taken in its whole extent, is one of the finest in the kingdom; it is in some parts bordered by handsome buildings, plentiful with trees along the centre. It is one of the largest parish churches in the kingdom, with three wide aisles and a chancel which include a great number of seats. The building was completed and consecrated on Easter Sunday, 1662. [Organ, xxvi. 2.] It was founded in the beginning of the 11th century as a chapel to the church of the Holy Trinity at Norwich, which had then a cell at Yarmouth. The living is a perpetual curacy, in the gift of the dean and chapter of Exeter; the whole of the income of the parish of Yarmouth and Great Yarmouth belongs to the dean and chapter of Norwich. St. George's church was built in 1716, under authority of an Act of parliament. The living is a curacy, and was in the gift of the corporation of Yarmouth, but they have recently sold the presentation, which is valued at 230l. a year.

St. Peter's, which was erected under the commission for building new churches, is a perpetual curacy, in the gift of the incumbent of St. Nicholas, and is of the net annual value of 160l. There is a small church in South Street, called St. Mary's church. The Wesleyan Methodists, Baptists, and other classes of dissenters have places of public worship. About one-third of the way from the town towards the mouth of the river is the Nelson column, which was erected in 1817: it is a fluted pillar with a statue of Nelson on top, and is 100 ft. far from the column are barracks, which were built at an expense of 120,000l. The building was used as a hospital after the battle of Waterloo: it is now unoccupied.

The chief business of Yarmouth is in fishery, herrings and smelt being the chief product. Some are conveyed by sea, and some by road. There are manufactures of slate and cork goods, which are sold to employ about 500 persons, chiefly women. Shipbuilding, rope-making, and other trades connected with the port, although small in comparison with the sea trade, are considerable.

The town is a borough with a market on Wednesday and Saturday. The borough is within the liberty of Yarmouth from its commerce as a seaport. It is the chief port for the exports and imports of Norfolk, Suffolk, and part of Essex. Perhaps not more than one-tenth of its shipping is employed in the fishing trade. It has also an extensive inland trade by the rivers Yare, Waveney, and Bure. The Yare is navigable to Norwich, the Waveney to Bungay, and the Bure to Aylsham and Wymondham. The Bure Navigation was opened in Easter week, but it is only for toys and gingerbread.

According to the Education Returns, there were, in 1833, 3 infant schools, with 107 children; 33 daily schools, with 1077 males and females; 1 boarding-school, with 25 females; 1 day and evening school for the deaf and dumb, with 40 females daily, and by 80 males and 50 females on Sundays; and 7 Sunday-schools, one of which was supported by the established church, and the others by different classes of dissenters.

On the 31st December, 1842, the number of sailing vessels registered at Yarmouth was 332 under 50 tons (total burthen 14,195 tons), and 328 above 50 tons (total burthen 36,547 tons); and there were four steam-vessels of 651 tons, and three above 50 tons. The number of sailing-vessels that entered and cleared coastwise from 31 Decr. 1841 to 31 Decr. 1842, was 2347 (total burthen 176,784 tons) inwards, and 1435 (total burthen 77,591 tons) outwards. The number of steam-vessels that entered and cleared was 501 inwards, and 501 outwards, the total burthen inwards as well as outwards being about 24,400 tons. During the same period there entered and cleared for foreign ports 150 vessels (total burthen 14,127 tons), and there were 70 vessels (total burthen 10,452 tons) outwards. Besides which there were five remote vessels inwards from and to the colonies. The net amount of customs-duty received in 1839 was 54,511l. 10s. 10d.; in 1840, the net amount received was 64,731l. 11s. 5d.

The Great Yarmouth Act, 1708, the Great Yarmouth Corporation Act, 1807, and the Great Yarmouth Improvement Act of 1821 consisted of a mayor, recorder, high steward, sub-steward, 17 aldermen (besides the mayor), and 36 common councillors. The first charter, which was granted in 1108 by King John, was confirmed and extended by later charters of Henry VII, Elizabeth, James I., and Anne, which last, granted in 1702, was the governing charter. By the Municipal Corporations Act the borough is divided into six wards, with 12 aldermen and 36 councillors. The borough of Great Yarmouth, which includes the borough of Yarmouth, comprises an area of 1270 acres. In 1841 there were 5183 houses inhabited, 104 uninhabited, and 61 building. The number of inhabitants was 24,060, of whom 10,537 were males and 13,523 females. In this number were included 49 persons in the Children's Hospital, 6 in the Royal Hospital, 223 in the workhouse, and 37 in the house of correction and borough gaol; but 173 mariners were not included. The population in 1801 was 14,485; in 1811 it was 17,977; in 1821 it was 18,047; in 1831 it was 21,115.

The parliamentary borough of Yarmouth returns two members to the House of Commons, as it did before the Reform Act, but the limits are now extended so as to include the whole of the borough. The number of parliamentary boroughs in 1841 was 27,550. The number of parliamentary electors on the register in 1835-6 was 1719; in 1840 the number was 1904, of whom 742 were 101, householders, and 1162 were freemen or were otherwise qualified to vote.

In the session of 1842 an Act was passed for making a railway from Yarmouth to Norwich. It is to be a single line, and it is intended to adopt the electric telegraph on it. By this Act so much of the Eastern Counties Railway as lies between Norwich and Yarmouth is superseded, and it has been projected to extend the line to Cambridge, but an Act has not yet been passed.

From the 1855 Book it appears that Yarmouth was a roadless demeans, to which belonged 70 burgesses. Henry III. granted a charter, with permission to fortify the town with a wall and moat. The wall had ten gates, and was strengthened with sixteen towers. The place must have been populous in the days of the Saxons, for less than 100 persons died there of the plague in 1348. In 1598, on the alarm of the Spanish Armada, a fortress with four towers, whence beacons might be displayed, was erected in the middle of the town. In 1621 platforms were constructed towards the sea, on which great fires were burnt.

As the navigation off the coast is dangerous, two beacons are kept in Yarmouth Roads. (Municipal Corporation Boundaries; Report on Statistical Returns; Population Returns; Party Documents.)
YARMOUTH. [WIGHT, ISLE OF.] 

YARN is the general name given to the threads which are woven into the various kinds of textile fabrics, whether cotton, silk, flax, hemp, wool, or worsted; the terms twist, mule-sheaf, organdine, tram, am, fine, &c., being particular names applied to particular sorts. A few words of explanation will here suffice supplementary to the details interpersed among earlier articles.

Yarn for cotton-weaving is of two distinct kinds, according as it is intended for warp or weft; each kind being varied to suit different fabrics. Water-twist or throttle-yarn (the first name having been derived from the water-frame by which this kind of yarn was formerly spun, and the second from the throttle employed) is non-twist, flax-yarn, and wiry, and is usually employed for warp in heavy goods, such as fustians, cords, or, for making sewing-thread. Mule-yarn (named from the 'mule' machine by which it is spun) is of a soft and downy nature, calculated for the warp in coarse goods, and for both warp and weft in finer fabrics. Arkwright's name is especially connected with the improvement of this kind; while Crompton effected most in advancement of the second. The spun yarn is distinguished by certain numbers, which indicate the number of ends or filaments contained in one pound, or in one, each half, or quarter of a pound, of 840 yards of yarn. The two kinds of machines are adapted for different numbers; thus, the throttle is not now often employed for yarn finer than No. 30 or 40, the higher numbers being generally spun by the mule. By substitution of these with others, and the movements in the machinery employed, the yarn is spun to so high a number as 250; and instances have been known of 167 miles of yarn being spun from one pound of cotton! In a modern throttle-frame, spinning No. 30, from 24 to 50 hands per spindle can be spun in eight hours, and from 69 hands with a mule the quantity varies greatly under different circumstances. The excellence and cheapness of the yarn spun by modern machinery has led to very large exports; thus we find from the Report of the Parliamentary Papers for 1842, that the quantities and declared value of cotton twist and yarn exported for ten years were as follows:—

<table>

It would be a curious inquiry, how many millions of miles of cotton yarn are exported every year; but this could not be determined without knowing the average of all the Nos. so exported.

Flax-yarn is not estimated by No., as cotton, but by numbers of bales of spinning. Three hundred yards form a bale of flax-yarn; 38 bales form a spin; 6 bales form a rand; 22 bales, or 21,600 yards, or 12 rands, form a dozen. In the process of preparation by spinning, the flax becomes separated into two qualities, the finer obtaining the name of fine, and the coarser that of tow; and the yarn spun from these two qualities is applied to different purposes. The spinning of flax-yarn is mostly effected by the bobbin-and-fly or throttle-frame; and modern improvements have led to the production of such fine qualities of tow that it is now used in combination with silk in pocket handkerchiefs and other fabrics.

With regard to hemp, besides the yarn employed for weaving into sacking and other coarse goods, the term 'yarn' is applied in rope-making in a different sense. The yarn in this case is in a loose kind, seamed, or cord, and it receives the No. according to the number of such strings required in making ropes three inches in circumference; thus, No. 18, 20, or 25 imply such thicknesses of yarn that an 18, 20, or 25 of these are required in making a rope of the dimensions just stated.

Silk-yarn has names applied to it not known in the examples just given. The silk is imported as a fine filament, or in the state of raw silk; it is twisted as a means of giving it greater firmness of texture, and then obtains the name of singles; two filaments are twisted together rather loosely, and formed into a yarn called tram, which com-

monly forms the weft or cross-threads of manufactured goods; lastly, two or more filaments are twisted separately into hard singles, and then twisted together in an opposite direction, forming a strong silken yarn called organzine, used generally for warp. Silk-yarn in the form of tram, organzine, that is, ready for the weaver, is called thread silk; and in this state much of our silk used to be imported; but since the removal of the import duties restrictions formerly laid on the trade, the raw silk imported bears very much a larger ratio to our throw yarn. Within the last few years, come largely into use in the preparation of yarn for the weaver; that is, the knotted, broken, or imperfect filaments which cannot be used in a throw form. Various kinds of yarn are now carded, roved, and spun much in the same way as cotton; and most of the cheap silk goods now sold in this country are made from yarn so prepared, not unfrequently mixed with cotton.

Yarn made from wool is called woolled or worsted, according as it is formed from short or from long wool, for clothing or from combing wool. The former of these so spun that the elementary fibres shall be in a finest feltin or fulling; while the latter has the filaments more or less twisted together, and the turns of the yarn are now carded, roved, and spun much in the same way as cotton; and most of the cheap silk goods now sold in this country are made from yarn so prepared, not unfrequently mixed with cotton.

Yarn made from mule is called mule-yarn, and is formed as it is from short staple of cotton, for clothing or from combing wool. The former of these so spun that the elementary fibres shall be in a finest feltin or fulling; while the latter has the filaments more or less twisted together, and the turns of the yarn are now carded, roved, and spun much in the same way as cotton; and most of the cheap silk goods now sold in this country are made from yarn so prepared, not unfrequently mixed with cotton.

YAR

eastward to Kostroma. At Rybinsk, between Mologa and Yaroslavl, it is joined by the Sekelina. All the rivers of the government flow into the Volga. The Mologa and the Sekelina are by far the most considerable. The lakes are 38 in number. The largest are those of Rostov (or Nero's) which is eight miles long and about five and a half broad, and the Nanchonero. There are many rivulets; and the whole government is not very well watered. The climate is rather severe: the winter, spring, and autumn short; the summer hot, and the purity of the air is very favourable to vegetation and to the health of the inhabitants.

The agriculture is the chief occupation of the inhabitants. The soil is on the whole only moderately fertile, and the corn produced is far from sufficient for the consumption of the inhabitants. Though the ground requires to be well managed everywhere, yet the want of eye and barley can be expected to yield sixfold, and generally four or five fold. Wheat and buckwheat yield only two or three fold. Oats are grown in large quantities; and Hemp, flax, hemp, and tobacco, paper, soap, and candles. There are many tanneries. The principal articles of export are Russia leather, sailcloth, the cloth called raven-duck, linens, cloth, some linned and linned sal, salt meat in large quantities, and horseshair; the imports are cotton, silk, Venetian, Russian, and English wool, manufactures, and manufactures. This gives rise to a very brisk trade. Yaroslavl, Rybinsk, Rostov, and Uglitsch are the greatest share in this trade.

The inhabitants are almost all Russians. The men are tall and handsome; the women are agreeable; White women, like a woman of Yaroslavl, is a common saying. They are of the Greek church, under the archbishop of Yaroslavl and Rostov, whose diocese is of the second class, and contains 833 parishes. The schools in this government are many, and their number has gradually increased since the beginning of this century, education is still in a very backward state. In 1832 (the latest date quoted by Schnitzer is 1835) there were 19 schools, with 72 monitors, of which 30 are ecclesiastical schools, with 38 masters and 1607 scholars. Kruzenstern, in 1837, does not afford later information.

YAROSLAV, the capital of the government, is situated, according to Hall, in 57° 25' N., and is surrounded by many stone houses, its 44 churches and three monasteries, gives it a striking appearance. It is however ill-built, in the Russian fashion, with narrow streets, some of which are principal streets, and the town is growing from St. Peterburg, is broad, and consists of handsomely done stone houses. The institutions for education are, an ecclesiastical seminary with 600 pupils, a gymnasium, a district school, and a school for the higher branches of learning, founded in 1803, by Prince Paul Demidoff, who endowed it with a capital of 300,000 silver rubles, and 3600 peasants.

It is called the Demidoff Lyceum, according to the revised statutes, which were carried into effect in 1834; they determine that there shall be a director, a chaplain, and eight professors, and that the number of students on the foundation, who are boarded and educated free of expense, shall be forty. After their education is completed they enter the public service. The lyceum has a very good library. There are in this city eighteen poor-houses, a foundling asylum, and a Bible Society. The manufactures are clothing; the linen and Russian leather of Yaroslavl are highly esteemed. It is the residence of the civil governor of the province, and of the military governor of Yaroslavl and Vologda. Its trade is of very considerable, and the merchants have a large bander. The population is 98,500 inhabitants.

The other towns worth notice are: 1. Rostov, situated on the lake of the same name (otherwise called lake Nero), one of the most ancient towns in Russia. It is six miles in circumference, and shows its former importance. It has several times suffered by war and fire. It now consists of the city and an extensive suburb. The city is surrounded by a rampart and a moat. It is in an unfavourable situation, being low, and surrounded by the river Volga. It is said that the kind of stone which is found here, where he has his principal cathedral, an ancient richly adorned edifice, and a vast palace, with a seminary. There are 24 churches in the city, and three convents, two of monks and one of nuns. Besides the bazaar the city contains 2500 houses, and 10,000 inhabitants. The women are celebrated for their beauty. The trade is very considerable, and the great fair, which begins at the end of February and continues for a month, is attended by at least 40,000 Russians, Armenians, Greeks, and Tartars, who bring goods to the value of 14,000,000 of rubles. 2. Uglitsch, on the right bank of the Volga, is likewise an ancient town, but the time of its foundation is uncertain. It is related that before the invasion of the Tartars in 1620, it contained 1200 houses, 24 convents, and 30,000 houses. The fire which destroyed it at that time annihilated its property. At present it has two convents, 23 churches, and a fortress built of wood. The streets are narrow and crooked. There are 7000 inhabitants, who have a considerable trade, and 16 manufactures.

3. Rybinsk, which has been described in a separate article.

(Hassel; Hörschelmann; Cannabich; Schubert; Schnitzler; Kruzenstern, De l'instruction publique en Russie.)

YEAR. Much connected with this article is to be found in KALENDARIOV, or YEAR Book, MOON, SUN, CHRONOLOGY, TIME, &c. We here confine ourselves to matters of useful reference connected with the length and subdivisions of the year, omitting discussion of points of history, which do not directly bear upon chronological reasoning.

The year is, roughly speaking, the period of time in which the sun makes the circuit of the heavens, and of the seasons of agriculture run through their course. In the tropical or civil year is the time in which the sun moves from a star to the same again; that is, the interval between the two times when the sun has the same longitude as a given star. The mean period is 365.2563612 mean solar days, or 365.2422414 mean solar days.

The anomalistic year is the time in which the sun moves from the vernal equinox to the vernal equinox again; and its mean length is 365.2422414 mean solar days, or 365.2422414 mean solar days.

The tropical year is the time in which the sun returns to its position (or nearest point to the earth) to its perigee again; and its length is 365.2595981 mean solar days, or 365.2422414 mean solar days.

The anomalistic year is the time in which the sun moves from the vernal equinox to the vernal equinox again; and its mean length is 365.2422414 mean solar days, or 365.2422414 mean solar days.

The tropical year is the time in which the sun returns to its position (or nearest point to the earth) to its perigee again; and its length is 365.2422414 mean solar days, or 365.2422414 mean solar days.

The anomalistic year is the time in which the sun moves from the vernal equinox to the vernal equinox again; and its mean length is 365.2422414 mean solar days, or 365.2422414 mean solar days.
sun is not nearest to the earth until it has passed the longitude at which it was nearest to the earth before. The tropical year is the year, when no distinctive term is applied; for the passage of the sun from the southern to the northern side of the ecliptic is the positive phenomenon on which it depended, though it is not correct to say that it is then that the succession of seasons begins.

The anomalistic year does not, and from the theory of gravitation most probably cannot, vary by any quantity which the human senses could appreciate; but the sidereal and tropical years vary very slowly in length. The reason is twofold. In the first place, the amount of the yearly precession of the equinoxes is slowly increasing; so that the part of the orbit by which the equinox moves backward to meet the sun becomes greater, or the duration of the year less. In the second place, the gradual motion of the equinox, combined with that of the perigee, brings the part of the orbit which the sun is saved from performing by the recession of the equinox into different planes with respect to the perigee in successive years; so that the excepted portion is in different years what would have been described in different times. The second consideration affects the sidereal year as well as the tropical; but since the both cause the effect is very small and slow, a few seconds in a thousand years, there is no occasion to do more than point it out in an article like the present. LaPlace makes the tropical year to be 13 seconds shorter than what it was at the time of Hipparchus.

The excess of the tropical year over 365 days has been given by different astronomers as follows:—

<table>

Whether the present length of the tropical year can be said to be determined within a second, we cannot collect from the writings of astronomers. The method of determining this length is by carefully observing solstices or equinoxes (that is, when the sun is in the solstices or equinoxes) at distant periods, and taking the mean year from the whole interval elapsed. Unless that interval were a whole revolution of the solar perigee with respect to the positions or fixed stars, the mean tropical year could not be determined, from observation alone, so well as it might be.

The civil year must, for convenience, begin with a day, and contain an exact number of days. But any exact number of days would have the disadvantage of the old Egyptian year (Soronic Period), namely, that the seasons would be thrown to all parts of the year in succession. Those who lived in the intense heat of March (when that month is near the autumnal equinox) would read old poets, to describe the spring as about to arrive, in that month, and abide to the past winter, and that before the poets would have become properly antient: this alone would be worth avoiding. Of the mode of doing it we shall presently say more, but in the meanwhile we have to observe that the real mean tropical year could not be determined, from observation alone, so well as it might be. The solar perigee with respect to the positions or fixed stars, the mean tropical year could not be determined, from observation alone, so well as it might be.

The Jewish, Christian, and Mohammedan religions all regulate their sacred anniversaries, more or less, by the mean tropical year. They have divided their year into months, according to the lunar revolution, though most of them have accommodated their years to the solar year by intercalated months. Now the time between two new moons, that is, the average time, is 29-5305897 days, or about 291 days. If then months were alternated of 29 days, twelve months would contain 344 days, and 11 1/4 days would be necessary to complete the Julian year of 365. This would amount to more than a month in three years. Taking the most exact values both of the lunar year and the solar year, and applying the method in Fractions, it will be seen that the year contains, over and above twelve months, something less than 3 months in 8 years; more exactly, something more than 4 months in 11 years; more exactly, something less than 7 months in 19 years; more exactly still, something more than 12 months in 334 years, less than 130 in 353, more than 23 in 567, less than 1356 in 2878. Taking the Julian year of the above figure as 365.25 days, we have less than 7 months of 19, less than 17 out of 40, less than 171 out of 400. The excess of 7 months in 19 years, which varies very little from the truth, whether as to the real, Julian, or Gregorian year, is the foundation of the celebrated Metonic Cycle, which, among the Greeks and all who have derived knowledge from them, has always been the foundation of the lunisolar calendar. It is now well understood that the Metonic moon, and not that of the heavens, is referred in the settlement of religious festivals; that also, a moon moving uniformly at such a rate as to make 235 lunations in 19 calendar years.

Owing to the alternation and retardation of the sun's motion in its orbit, the lengths of the four-annum seasons are different as follows:

- From vernal equinox to summer solstice: 92-29
- From summer solstice to autumnal equinox: 93-14
- From autumnal equinox to winter solstice: 91-16
- From winter solstice to vernal equinox: 93-11

We shall now state the principal facts connected with the years of the nations who are most connected in history.

The Jews, from the time of their departure from Egypt, began their year with the vernal equinox in all their reckonings, retaining the old beginning, which was the autumnal equinox, in all civil purposes. They reckoned from the new moon near the equinox, making twelve months in the year, each of 29 or 30 days, with an intercalary month once in three years, the Jews deriving themselves from the necessity of any but a sidereal circulation. They in this year determined the beginning of the year to slide away from the vernal equinox, but this their rites prevented them from doing, and the sacrifices required the offering of various species of agricultural produce, dependent upon season. They had also at times of the year: the necessity of providing young lambs, for instance, at the Passover, obliged to keep this feast at one time of the solar year, and not at the full moon following the vernal equinox, by which they managed their calendar in the first instance does appear; but as we know they once depended upon seeing sight of the new moon to settle the beginning of a month, and only used the 23 or 30 days when they fixed their object, we must infer that they were in the habit of making the intercalary month something that could be done, as remarked 'by the editor of the Verifier les Dates,' while they were in possession of the time, and within reasonable distance of each other.

There is not any trace of astronomy in the old writings of the Jews, and we are at a loss to know of any knowledge of it from Egypt. But during the Captivity they acquired from the nations among whom they were thrown, either a period of 84 years or knowledge to construct one. Several of the Fathers mention this period, and state that it had long been used by them. The first has the appearance of a Calippic Period of 76 years but a day, with the period of 8 years added, in the position that the making of three intercalary months would be as the regular sources of chronology, and only after this contained in the Calippic period. But it is not the case, and 84 years is really not so near an exact number of lunations as 76 years but a day, nor of the early Christians used this period, and therefore not a correct period, and they were therefore corrected by the Emperor Augustus. Easter, which afterwards was corrected by the Council of Nice.

The modern Jewish calendar is regulated by the revol of nineteen years, and its lunar years contain various sects which refer to the religious ceremonies. They are presented as an exact date by the Jews, reckoning from the beginning of the month of Nisan, much more easily found than the Hipparchian. Ptolemy had 29d. 12h. 44m. 3s.; reject the fraction, as we so often done, and we have the Jewish value; and it happens that Ptolemy and Hipparchus had got just a little.
more than the fraction too much, this saving of trouble is an accidental correction. There is no accompanying value of the sun's motion more correct than that implied in the Julian.

The Hebrew calendar, or common sex of England, are.

The English months in which they severally most frequently begin, with their number of days:

For the Egyptian year, see SOTHIC PERIOD.

The twelve months of the Athenian lunar year bear the following names: but there is a slight difference of opinion about the order in which they come, some putting:

1. **Greek**:
   - January
   - February
   - March
   - April
   - May
   - June
   - July
   - August
   - September
   - October
   - November
   - December

2. **Roman**:
   - January
   - February
   - March
   - April
   - May
   - June
   - July
   - August
   - September
   - October
   - November
   - December

This is reckoned by its position with respect to the next simply denominated day, be it Kalends, Noneis, or Nones. Thus the third day before the Nones of January, the day of the Nones itself counting as one, is **ante diem tertium nonum Januarias**, a singular mode of speech, which does not appear to have been fully explained. It is generally rendered as if it were diem tertium ante Nones Januarias, the third day before the Nones of January. These designations are usually written in a contracted form in the manuscripts, and these contractions are usually all that are to be found in chronological works. (See Collin. ii. 2.)

**Reference**

- Aprilis, Maius, Junius, Julius, Augustus, September, October, November, December.
- The first of each month is its kalends, Kalendae Januarii, February, &c.
- The number of days in each month is well known by the old rhyme. The 13th of some months, the 16th of others, is called the day of the Ides (Idus): and the ninth day before the Ides inclusive is called the nones: Noneis, and every day is reckoned by its position with respect to the next simply denominated day. Thus the kalends of January, the day of the Nones itself counting as one, is **ante diem tertium nonum Januarias**, a singular mode of speech, which does not appear to have been fully explained. It is generally rendered as if it were diem tertium ante Nones Januarias, the third day before the Nones of January. These designations are usually written in a contracted form in the manuscripts, and these contractions are usually all that are to be found in chronological works. (See Collin. ii. 2.)

The intercalary year, when introduced by Caesar, had the additional day bestowed upon it by doubling the sixth day before the kalends of March, whence the year was called *bissextile* (BISSEXTILE) so that the month of February ended thus—

|----|------|------------|

There was thus ante dies sextum kalendas Martias posteriorum et ante diebus sextus kalendas Martias priorum. The general rules of this clumsy calendar are, that the ides are on the 15th of March, May, July, and October, and on the 30th of all the other months: that the nones are always on the eighth day before the ides, according to our mode of counting: that the kalends are always on the first day of the month: and that the intermediate days are numbered as before. As numbering is required, backwards from the kalends, nones, or ides, each of these reckoning was always in counting backwards from the ides.

The original Roman year is variously stated by historians at twelve and ten months: the latter seems the best supported and the old year wanted by Caylus and Foucher, and had Quintilius and Sextilius in place of July and August: these two months yielded their names to those of the two emperors who reformed the calendar. Numa Tarquin introduced what was meant for a lunar year of 350 days. The year is supposed to have been related to the solar year by the decemvirs: but there is great deal of discussion upon all these points, which will be quite out of place in anything but an historical notice.

In the year 45 B.C., the correction made by Julius Caesar with the assistance of Bombæus, was indeed the preceding year having being lengthened into 445 days, order probably that the new era might fall at the moon following the shortest day. The pontiffs named who came after Julius Caesar made the meaning of the correction equal to a bissextile day. This year was said one every fourth year, counting the last bissextile, according to their interpretation of Caesar's nickname which the fourth numbers beginning from I was not 6, 9, 13, &c., but 4, 7, 10, &c. This was corrected in Augustus, when Pontifex Maximus &c. decided that three bissextiles from that date should be called (being as many as had been then superadded to the calendar in years preceding), and that the mistake should be avoided in future.

No further chronological difficulty occurred until the third century, when disputes about the mode of determining Easter-day began to perplex the Christian world. It is commonly stated that the Council of Nice made the adjustment which lasted until the Gregorian reform. This is not correct: the council, according to Eusebius, others, only ordained that all Christians should keep Easter on one and the same day, and referred it to the bishop of Alexandria to settle what, agreeably to the remembrance of the subject, that of the event shall be in each particular year. By what follows, it appears that this point adopted the Metonic cycle, and he certainly could not have done better, having no licence to make a fixed independent of the new moon.

The Gregorian reform (so called;) we will not to give reasons for our protest against the word; was consequence of the desire that the seasons remained in the same months for ever. The Julian calendar gave a year which is too long at the rate of 3 days in years nearly. At this rate, in 24,000 years such a midwinter would have fallen in December. It was not so much to avoid this, so to keep the festival in the same parts of the year, that is, in the same kind, that the correction was insisted on. The change has been discussed by individuals and even by councils during preceding centuries, and was finally decided on by Gregory XIII, with the authority of the Council of Trent. In 1582 the reformation was carried into effect: ten days were struck out of the reckoning which would have been the 5th of October being denominated the 15th, so that the days 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 of October, 1582, never existed in Italy, Spain, which accepted the change as soon as so to be speedily. In the Alphabetic tables, which were consulted, are by a day in this matter, and even the episcopal tables have been suppressed. The consequence is (Porson or Ravenrous p. 449), that the equinox varies between the 22nd and 23rd of March.

Leaving out the parts of the Gregorian calendar which relate to Easter, we proceed to the alteration of intercalation. This is as follows:
number is divisible by 4 is leap-year, except only when
the number ends with 00, in which case it is not leap-year,
except when the preceding figures are divisible by 4.
Thus 1800 is not leap-year, but 1804 is.
If we take the
most recent value of the length of the year, 365.2422144
mean solar days, and apply the method in Fractions,
Convoluted, we shall see that the excess of the real year
above that of 365 days is something less than 1 day
in 4 years, more than 7 in 29, less than 9 in 33*, more
than 35 in 150, and less than 242 in 999. This last excess,
225 days, is so very remote, that it is most
fortunate that Gregory’s advisers did not know it, for they
would in that case have adopted it and saddled our world
with a most troublesome omission of intercalations for the
benefit of posterity of fifty thousand years hence. As it is,
the excess of 1000 mean Gregorian years above as many
of 365 days is 2:2:5 days: it would have been nearer the
truth had it been 242:242 days. Accordingly 1000 mean
Gregorian years are too long by about a quarter of a day;
more correctly, 3600 years give an error of a day. De-
lambre proposed that the Anni Domini 3600, 7200, 10,800,
&c. should not be leap-years, which they are to be in the
Gregorian calendar. If the world should last till A.D. 3600,
we hope the correction will be called by Delambre’s name:
by this time a hound then has perished, still more will
that of the present article, so that there is no use in pro-
pointing the point.
The European years have been made to begin at such
different periods, that the historical inquirer is frequently
perplexed; and those which relate to our country
in Periods of Revolution, p. 440. The 25th of
December, the 1st of January, the 1st of March, the 25th
of March, and Easter, have all been in use.
In regard to the common year as it now stands, there
seems to be no law by which it will be used, or by
which it will be corrected. We can hardly forbear to quote the verses which are so
exceedingly in use, but we will do it from a version of 1596;
DAYS OF THE WEEK.

Turkev, p. 405, does very well to determine the com-
mencement, except that when the Christian year con-
tains the commencements of two Mohammedan years,
the rule will only give one: the other however may
easily be inferred.
When the comparison of dates is to be very close, an easy rule will be sufficient, and
recourse must be had to either in the list in the ‘Art de
vérifer les Dates,’ or to the rule and supplementary
tables in the ‘Companion to the Almanac’ for 1830.
The year 1 of the Hegira begins from July 16, 622, and the year 1200 begins January 10, 1844. But two
years after the year A.D. 1583 (911 of the Hegira: the ‘Art de
vérifer les Dates’ gives two commencements for every
year (the second twelve days later than the first), which
it says, according to the old calendar and the new one:
no mention is made of this distinction, that we can
find, in the introduction to that work, nor in other common
sources. Our ‘Nautical Almanac’ gives the commence-
ments according to the new calendar.
The unwonted attempt made by the French, during their
first Revolution, to alter the names and dispositions of the
years and months, might now be quietly consigned to ob-
liation, if we were not that many excellent works bear the
revolutionary dates upon their title-pages, and political
conferences are frequently referred to them during the
short period of their Descent. The year 1 of this period
was made to begin September 22, 1792; each period of four
years, or Franciad, had an Olympic or bisextile at its
end. The three omitted leap-years of the Gregorian correction
were to be very much like the rule as before, and the years
ending with 00: and the 4000th year was not to be
leap-year. The year consisted of 12 months of 30 days
each, with five sacred days at the end, dedicated to
Virtue, Genius, Labour, Opinion, and Reward; the bi-
eximal or double day being appropriate every fourth year to the re-
newal of the oath of Liberty. Each month had three
days. The months were—

But An XIV. did not live half its days: for on Jan. 1,
1806, the Gregorian calendar was resumed, and the
republic, which had legislated for the 4000th year of its exis-
tence by name, wore its own liver just one day and a
quarter for every one of those years.
YEAST, or FERMENT, a substance which is deposited
in an insoluble state during the fermentation of wine,
beer, and vegetable juices. This substance, as is well
known, is employed to produce fermentation in saccharine
solutions. According to Liebig, the insoluble part of
yeast does not cause fermentation, for he states that if it
be carefully washed with water, care being taken that it
is always covered with water, the residue does not produce
fermentation.

Ferment, according to the same authority, does the so-
luble part of yeast excite fermentation until it has been
allowed to cool in contact with the air, and to remain some
time exposed to its action; if this state of the fluid is
increased in solution of sugar it produces brisk fermentation.

Ferment is a product of the decomposition of gluten, and
when added to a solution of pure sugar, it gradually dis-
appears: but when added to a solution of sugar which con-
tains gluten as well as sugar, it is reproduced by the dis-
position of the gluten, in the same way as it was origi-
nally formed.
According to Professor Graham, the action of yeast and all other fermenters is destroyed by the temperature at which water boils, by alcohol, by acids, salts of mercury, sulphurous acid, chlorine, iodine, bromine, by aromatic substances, volatile oils, and particularly empyreumatic oils. Smoke, and a decoction of coffee; these bodies in some cases combining with the ferments or effecting their decomposition.

YEDO. [JAPAN.]
YEKATERINOSLAV. [ERKATERINOSLAV.]
YELOW. [Calleco Painting; Dysing.]
YELOW, FEVER, a disease of frequent occurrence on the eastern and western coasts of America, in the West Indies, in Africa, and in Europe on the southern shores of Spain. The prevalence of this disease in these countries, its great fatality, and the mortality it produces in navies and armies, have attracted much attention towards it both from governments and medical men. This disease has been described under other names, such as typhus icterodes, Buban fever, bilious remitting fever, vomito negro, vomito prieto, endemial cases, mal de grain, &c. Although this disease has a very distinct history, and can be easily distinguished by the mass of symptoms it presents, yet it is difficult to give in a few words anything like a satisfactory definition of the disease, or to state one of the more recent attempts on this subject, gives the following definition: a disease in which yellowness of the skin, partial or general, and towards the fatal termination, vomiting of a black or dark brown fluid, are frequent symptoms. There is no means consentaneous to this disease, and the fever would be of little use for distinguishing the disease, and perhaps after all it will be found that yellow fever is only a modification, under peculiar circumstances, of some primary form of disease in which all others originate. It is certain that this disease has many symptoms in common with other fevers, and that it assumes the types of the common, continued, remittent, and intermittent fevers.

It has only been within a comparatively recent period that this disease has attracted much exclusive attention, and on this account some writers regard this disease as one altogether of modern origin, and fix the date of its generation during the latter part of the eighteenth century. But although no accurate account of this disease as distinguished from other fevers exists, previous to its appearance in the island of Grauuda, in 1793, yet there can be no doubt that the records of the occurrence of destructive fevers in those districts in which the yellow fever now occurs, refer to the same disease.

The record of yellow fever is mostly preceded by well-marked premonitory symptoms. For two or three days previous to the attack there is a depression of spirits and an unnatural inactivity without any sufficient accountable cause. There is sometimes nausea with a creeping sensation in the loins, back, arms, face, and head. The eyes are suffused, dull, and heavy, and the sight is dim and sometimes double. There is often slight confusion of mind and a kind of drowsy restlessness. The appetite is bad, the taste is perverted, and the bowels are either confined or relaxed. The skin is in some cases permanently dry, or there may be sweating after slight flushes of heat. The pulse varies considerably; it may be small, quick, irregular, or soft and full. Such symptoms do not appear to be those of an affections of the heart, but the ap¬peared immediately with a shivering, the indication of the near approach of the worst symptoms. Sometimes during this premonitory stage there may exist a yellowness of the eyes and of the skin, and also a vomiting of bilious matter.

The commencing of the febrile attack mostly takes place at night; after the shivering, a state of general excitement takes place, which sometimes increases to a very distressing and uncomfortable extent. Pains occur in the head, in the eyeballs, in the back and loins, and cramps in the gastrocnemius muscles. The patient prefers the recumbent position and lies upon his back, but is in a state of great restlessness, frequently throwing his arms about, more especially above his head. The face is usually flushed, sometimes of a crimson hue, and occasionally swollen so as to appear bloated and heavy. The eye has a heavy drunken appearance, is injected, swollen, and moistened with tears; the pupil is generally permanently dilated, and the balls seem protruded as if they would start from their sockets. The skin is in most cases flushed, and warmer than natural. The pulse is accelerated, full, and compressible; in some cases however it is usually slow, and under these circumstances the skin is unnaturally cool. The tongue is swollen and coated with a white mucous paste. Vomiting does not usually occur at this stage. The bowels remain more or less constipated, but easily acted on. The intellectual faculties are more or less deranged. These symptoms last for six to 13 hours, when the second stage may be said to commence. The general excitement sometimes persists, but the com¬mence becomes deeply expressive of some. The congested state of the eye begins to yield, and to place a slight yellow tinge is observed. This généra¬creating till it extends down the face of the member the yellow tinge spreads itself over the whole skin, and to the whole body, according to the complexity of fever, various colours, from a pale lemon to orange or saffron colour. The pulse becomes more thickened in frequency. The coating on the tongue becomes yellow, and this organ towards its root and edges and tips has a clean and dry red appearance. To the stomach now becomes irritable and painful on press. Food is immediately rejected. There is a degree of debility, and in very few cases this is not accompanied with any severe retching. The vomited are generally ingesta and a clear fluid, and sometimes is bile discharged. The alvine secretion is mostly natural. The urine is diminished in quantity as generally the remaining symptoms in the larynx and hunger remain. As death approaches the exhaustion becomes greater, respiration is hurried and noisy, the surface and extremities become cold, and covered with a general clammy perspiration. In some the last moments are marked with a pain and a strong convulsion which no others death is. To come upon the patient unawares.

These general symptoms are by no means present in every case, some having been constantly observed by medical writers, whilst others have never met with in all. Amongst the symptoms which have not been mentioned by some writers as pointing out important differences in the character of the disease, these are inflammatory, adynamic, and malignant. The malignant occurs in full plethoric habits, and the whole the symptoms indicate a greater amount of excitement, activity, and the disease proceeds to a fatal term sooner. The adynamic variety occurs in those who have deficient animal vigour. In this form of the disease the removal of the premonitory symptoms appears to be made to the progress of the disease, and patient sinks in the course of four or five days. The lignant form is the worst of all. From the first the patient seems attacked with death. All the symptoms from the beginning, and most awful. Persons seldom recover from this state, and many die during the first twenty-four hours of the attack.

The nature and origin of the black matter which is so often observed in the tongue and mouth is the subject of much investigation. The most correct view is probably that of Dr. Fordyce, who considered that it was formed with the incrustation of the tongue, gums, and lips caused generally in violent fevers, and that probably the inflammation is produced by the surface of the mouth, even from the duodenum and jejunum. When eaten and given to animals, it produced no bad effect upon them and an atmosphere impregnated with its exhalation do not appear to be injurious. Under the microscope the appearance of minute scales of smoky wire.
ark brown or red colour. It is probably nothing more than the globules of blood broken down, which have oozed upon the surface of the stomach, instead of an ordinary secretion, and perhaps under the influence of severe vomiting. It may frequently be mixed with bile, but it does not appear in the majority of cases to be the character of bile at all.

It is difficult to give any definition of yellow fever, so that it is difficult to give any rules by which it may be distinguished in individual cases from other diseases. Its occurring generally in several individuals at the same time, soon leads to the development of the group of symptoms upon which we are to depend and by which it may be distinguished from allied diseases.

The mortality from this disease is always considerable. It is usually much greater at the commencement of the epidemic than it is at subsequent periods. In some instances, all the cases occurring for the first few days after breaking out of the fever have proved fatal. Sometimes however the disease is very mild, and but few fatal cases occur. The mortality is generally greatest amongst the negroes and mulattoes, the disease being very rare in the white population. As a general rule, however, that which regards its cause has been discussed with the most zeal and bitterness. We cannot here go into any details of this discussion, but the great point in dispute is the contagiousness of this disease. Many of the early writers have denied that it is contagious, and on this account persons who have been exposed to its influence are obliged to submit to the most rigid quarantine regulations. But during the last twenty years medical men attached to the various troops and hospitals where this disease has appeared have almost entirely abandoned this notion, and the result is an increasing conviction of the non-contagiousness of this disease. But whilst there is much evidence to prove that this disease is not communicable by any morbid matter that may be generated in the human body, yet it is a fact, that whilst it is not contagious, yet this cause is too general to account for the exceedingly local character of the disease in many instances. Cases are recorded in which the inhabitants of particular parts of a town, the one side of a street, or even one room of a blockhouse, whilst all the rest of the inhabitants have been affected, the disease under the circumstances is frequently accumulated a yellowish rosily. The lesions in the chest are not remarkable. The pustule is generally distended with air, its mucous surce is occasionally effused with blood, and its vessels reddened. In some cases the latter may be seen, from which by slight pressure oozes a fluid which appears to be the 'black vomit.' The small vesicles participate in some measure in the lesions of the stomach. The liver is sometimes engorged with blood, and sometimes it is hard and dry. The spleen is generally increased in volume and softened.

In the treatment of yellow fever much difference of opinion has prevailed, according to the opinions of those who have been affected. Under the circumstances are frequently the most efficacious treatment. But the first thing to be considered is the necessity to consider the nature of the case, and the most essential point in it is to have the patient in bed. As is most often the case in the treatment of fevers, that in their course exhibit both active and low symptoms, two very different plans of treatment have been recommended: the one antiphlogistic, the other stimulant. Without entering into a theoretical discussion of the merits of these plans of treatment, it may be stated that both may be rendered necessary in various stages of the disease. In the majority of cases the patient will bear blood-letting at the commencement of the disease. The blood ejected is the only mode of passing off, and it is advisable to have recourse to it, as in most cases the stomach is irritable to bear the introduction of medicines. Bloodletting should be carried to the extent of producing a decided effect on the symptoms. As a general rule, this remedy should not be had recourse to after the second day of the attack. The next remedy in importance is mercury. Some of the best writers on yellow fever, and those who have had the largest experience, consider mercury as their sheet-anchor in this disease. It should be administered in doses of sufficient quantity to affect speedily the mouth. Many practitioners who use this remedy do not employ it as an absolute cure, but only in those cases in which the inflammatory symptoms are severe. In addition to these means, purgatives, emetics, antimonials, and cold affusion have had their advocates. These remedies are however all of them adapted more to particular states of the system than to the disease itself, and should be administered according as circumstances arise which may indicate their necessity. With regard to the tonic or stimulant system altogether, it may be stated that this practice is now almost entirely condemned by British and American practitioners. In cases where the disease assumes a remittent form, quinine may be administered with advantage; but the administration of bark, so much in vogue amongst the Spanish medical men, is now very generally condemned. Dr. Stevens particularly insists on the administration of saline medicines in yellow fever, in which there is no objection, provided the stomach will retain them, and they probably have a beneficial effect on the system according to his theory.

The morbidity of this disease is extremely high. It is fatal in the great majority of cases, and in many instances the disease has been known to terminate in a few hours after the appearance of the first symptoms. The convalescent period is almost as severe as the active period of the disease. The cases of convalescence are by no means rare. But whilst there is much evidence to prove that this disease is not contagious, the theory of parasitism has not been able to explain away, or to account for, the phenomena that occur, but as leading to highly beneficial and important results in the treatment and prevention of this disease.
the centre of the breast-feathers and of those of the sides and lower tail-coverts a longitudinal brown spot; yellow of the abdomen pale.

Varieties.—Some parts of the body sprinkled with white in the yellow. The white, or yellowish-white. Wings and tail often pure white.

Geographical Distribution.—Denmark, Norway, Sweden, in short, throughout Europe to the Mediterranean, England, Wales, Scotland, and Ireland (resident), Orkney and Shetland (visitor).

Pennant quotes the Bruant of Belon (L'Histoire de la Nature des Oiseaux, p. 366) as this species, and the description seems to warrant the quotation. Belon considers the bird to be the Asbro (Anthus) of Aristotle (Hist. Anim., ix. 1); and remarks that the Greek of his time did not call it by the antient appellation in their tongue, but by the Latin name Florus, car ils ont esté dominers par les Latins, dont ils ont renou telle dictio. It is the Bruant of the French generally; Serramolle and Zivolo detta gialla of the Italians; and, according to the Portraits d'Oiseaux, Hortolano, Cia, Megliarina, Verzerot, Paterizzo, and Spatardia of the same people. It appears to be the Groning and Galespink of the Swedes; Goldammer, Ammering, and Goldammering of the Germans; Geel—Gerst of the Netherlands; Voit, Yellow Yoldrin, Yellow Yoclely, and Yellow Yelrod of the modern British; and Linos feyen of the antient British.

M. Temminck states that a species closely resembling this in the tints of its plumage inhabits Japan; but that it is specifically characterized by a shorter and rounded tail, and by a small black mark which encircles the bill of the male. For this species M. Temminck proposes the name of Emberiza perennis.

Habits. Food, etc. of Emberiza citrinella.—The food of the Yellowhammer consists of grain, seeds, and insects, and in winter it joins the flocks of greenfinches, chaffinches, and other congregators in the fields and farm-yards. In the summer the notes of the male, so familiar to every traveller, are repeated five or six times, and when the last drawn out, ring almost incessantly from the road-side hedge. Sometimes the form of enunciating this strain is slightly changed; thus, the cow-boys, according to Mr. Main, hear in the Yellowhammer's song the following words—

'A little bit of bread, but no cheese.'

The nest, which is ordinarily made on or very near the ground, sheltered by a bush, in the tangled grass of a hedge or ditch, is framed of moss, roots, and hairwell interwoven. The bird breeds late. The four or five pale purplish white eggs are streaked or veined and speckled with dark reddish-brown, and the male takes its turn upon them. The brood is generally out and about early in June.

These birds are caught and fattet for the table with the Oritalan in Italy, whence probably one of the Italian names above noticed.

In Scotland,' says the author of The Darker Super-

stitions' of that country, 'the yellowhammer has been con-idered mystical from three drops of the blood of Satan in its body, but further explanation is unknown.'

In the Portraits d'Oiseaux the following quaint's printed under the cut—

'Non sans raison Bruant je suis nommee ;
Vol et chant aussi semble le brun,
Le cheval vole en ma misfortune
Je suis nasse a la nue mexane.

The last lines allude to the supposed enmity between the bird and the horse, which Belon thus states in his old French:—'Il a haine avec le cheval : que le il dece de son pasture de l'herbe, de laquelle il se nourri sa. Il fait qu'il voix qui vide et son yeux qui tourne, se voyant contre le cheval il espouse, et le fer le.
Il n'a guere bonne veue : et par ce il est qualqu'ci du cheval, il se trouve au depouruene.'

YELLOW RIVER, called by the Chinese Hoang-ho, and the largest river in Asia, and the second in magnitude in the Chinese empire. It drains the seven provinces of China Proper, a small portion of Mongolia, and the greatest part of Tangut. The Hoang-ho rises in the high snow-covered mountains which fill up the greatest part of the southern districts of the last-named country [Tangut, vol. xxiv., p. 323], at a distance of 280 miles from its mouth in a straight line. But as there perhaps no river on the globe which changes so frequent the direction of its course, the exact course is computed by Ritter to exceed 2800 miles, amounting nearly to double the distance between source and mouth. The countries drained by the Hoang-ho cover an area of 74,000 square miles, equal to that of the British Isles. Of all the countries of Western Europe lying west of a line drawn from the most northern recess of the Adriatic to the bouchage of the river Oder in the Baltic.

The sources of the Hoang-ho have never been visited by any European, and are almost unknown. The map and section above the river, which has no communication with the sea. They therefore imagined that Tartary was, the water is lost in Lake Uron [Travels in Nanlu, vol. xxiv., p. 364], constituted the upper course of the Hoang-ho, and that it was connected with the two sources of this river by a subterranean channel. Were these true sources were situated was not known until Mr. Kuphol, a Mongol who travelled towards the end of the thirteenth century, sent some sons to discover and to explore the country surrounding them. According to the report made by these people, the sources of the Hoang-ho are found in a deep valley between the ranges of the Bayan Khara Mountains on the south and the Kuen-kuin range on the north. In the pressure more than 100 springs are stated to rise to a level plain about 40 miles in circumference. A great number of springs has resulted from a strong current seen from a distance the stars of the sky. Hence this tract is called the Mongol, Hotun Nor, or Star Lake, and by the Chinese Sing-su-hai, or 'the sea overspread with stars.' The same is brought up by these springs on a shorter distance, two lakes, called Ala-nor by the Mongols. The Ala-nor is therefore to be considered as the true source of the Hoang-ho.

Upper Course.—The Ala-nor lies in 35° 39' N. lat. and between 106° and 77° E. long. The river issuing from the lake on the east is called Tahi-ping-ho (the river with the red banks), and after having been joined by three tributaries it falls into the Alpine Lake Uling-hai, from which issues under the name of Hoang-ho. It then passes the immense ranges of the Kuen-kuin, runs for more than 300 miles southward, and resumes its eastern course and continues in that direct for about 100 miles. To avoid the high mountains of the Bayan Khara range, which stand in its way, the Hoang-ho turns with a bold sweep to the west, as if it were return to its sources, and flows in that direction about 100 miles, surrounding on three sides the eastern expanse of the Kuen-kuin Mountains. But the waters, masses of the same system oppose its course west, and it turns by degrees to the
Mongolia. [Mongolia, vol. xv., p. 232.] It is certainly remarkable that in a course of more than 500 miles from Mongolia to its mouth, the river Hoang-ho bends towards the south, not a single river above the size of a rivulet increases its volume of water, and this fact more than any other indicates the extraordinary nature of the country which extends along this part of its course.

Where the Hoang-ho flows through a plateau very imperfectly known, as it has been seen by the Jesuits only at a few places, where they were obliged to pass it. Below the mouth of the river Targhuenu (40° 30' N. lat.) its width amounts to about 800 feet, and further south, at Paoto-tsheou, it has increased to 1,400 feet, and so rapid, that the imperial court required three days to pass, though great preparations had been previously made for that purpose. It is observed that at this part the current can only be stemmed by vessels when they have a strong wind in their favour, and that it cannot be used as a regular means of water-communication. Farther down, at Lung-men (the throat of dragon), the bed of the river was originally narrowed by projecting high rocks, and also at some other places, but the rocks have been removed by art and the bed of the river thus widened. This proves that the lowest part of its middle course is used as a navigable channel. In these parts, but the place is not more exactly indicated, are cataracts or rapid, which by this time are compared to the Weihai.

Middle Course.—Below Lant-tsheou the Hoang-ho turns toward the sharp bend northward, and flows in that direction, with some deviation to the eastern, through five degrees of latitude. Its course is such which has already been de not short all about 430 miles. When the river has passed 41st lat. it meets the range of the In-shan Mountains, by which its course is turned to the east. After flowing near 1°N. lat. about 180 miles eastward, the mountains bordering on China Proper on the north oppose its progress in that direction, and it turns to the south and runs through the mountain-region a space of about 520 miles (seven degrees of latitude) until it enters the great plain of desert mountains, which is compared to the Weihai. Its middle course amounts to about 1130 miles.

Where the Hoang-ho issues from the narrow valleys which rapid current has scooped out in the snow-covered sky masses of Tungut, and at the place where it begins to descend, it indicate them which have already been de, the fortress Tse-yish-kuan is built. The valley high extends from this place to Lant-tsheou and hence north and east to the mouth of the Thian-shui (40° 30' N. lat.) is compared by Peter Martini, a native of the river, that runs about 250 miles by the name of Innerwuch, which shows that the river has left behind the more elevated parts of the mountain-region, but is still traversing the part of Che. In this part of its course, especially above ant-tseou, the volume of its waters is greatly increased by the south. Rocks and cliffs by the name of Kahan-yeou, originating in the Nan-shan, flows to it from the northwest, and appears to have a course of more than 800 miles.

At the mouth of the Shian-shui the mountains on the river disappear, and are replaced by a hilly plain, in which tracts of fertile and cultivated land are mixed with sandy hills. Proceeding farther north the extent of the fertile grounds decreases until, opposite the entrance to its affluents, the total extent of land placed by the Steppe of the Ordos, a desert whose surface is mostly covered with sand-hills, destitute of wood, near of vegetation, but in the numerous depressions between them are extensive meadows and pasture-grounds, enclosed by the extensive mountainous ranges, inhabited by a very bad crowd of animals. Few and limited tracts this country are cultivated, but the Tshoros Mongols within their numerous herds occupy nearly the whole of the plains surrounded by the northern bend of the river. On the west of the river, in the vicinity of the town of Ning-hia, it is a mountain-range called Holang Shan, which however does not rise to a great elevation, probably more than from 3000 to 4000 feet above the surface thereof, and is stated not to exceed 3 or 4 miles in isth. Its eastern declivity is an overgrown with forests. The tract of country between the Holang Shan and the is several miles in width, and well cultivated, its soil, richly sandy, being rendered fertile by numerous canals that are fed by the lower reach of the river. But this fertility increases in proceeding northward, and disappears entirely when the river passes 40° N. lat. In these parts Ritter sees the greatest elevation of the Gobi, or Great Desert, if the river at its most northern course runs in a valley, which is reached at the extent of that elevated country, but it does not appear that it has a bottom along its isth., nor that any tract contiguous to it is cultivated. The steppes of the Gobi being wrapped in uninterrupted rocky wastes, and we do not know how they are reached, are compelled to run eastward until it arrives at the numer-

ranges which traverse Northern China east of the mountain, and are offsets of the ant-tseou plains of

The great road leading from Peking to the southern provinces, especially to Su-cho-an and Yun-an, lies through the lower part of this valley; and from Pekou it heads
southward over the Pe-ling range by a mountain road, which, for the difficulties it presents, and the art and labour with which they have been overcome, does not appear to be inferior to the road over the Simplon in Switzerland. This road leads to Mian-kian, on the Han-kian, and thence over a less mountainous region to Tshung-tu-foo.

After the Hoang-ho has left the pass of Thung-kian, it enters the great plain of Northern China; but not immediately the river, for more than 150 miles its course lies through a hilly country, which extends eastward to the mouth of the Lu-ho. Along the river however is a low tract, which grows wider in proceeding eastward; and its soil, although formed of alluvium, is very fertile and well cultivated. The hills also, having generally not very steep declivities, have been subjected to cultivation by means of terraces. Having been joined by the Lu-ho, which river runs in the same direction as the Hoang-ho about 200 miles to the north, and river passes to the lowlands, in its place, according to historical records, the Hoang-ho in former times divided into two branches, of which the northern ran to the north-east and north, and fell into the Gulf of Petchelli. This arm seems to have been the principal branch of this river, and the town of Kai-fong-foo, the source of the river, occurs, which are so extensive that they can only be traversed in several days. In these swampland grounds originates a river, called Wei-ho, which runs northward, and whose waters in the lower part of its course are used to form the Great Canal. It is very probable that this is the antecedent channel of the northern branch of the Hoang-ho.

At present, the Hoang-ho runs in one channel eastward, and near the town of Kai-fong-foo it borders on a very low and flat country, which is exposed to occasional flooding, which in China are more feared than war, plague, and famine. As the adjacent country is very low, it was at an early period considered necessary to protect it against inundations by dikes, built of quarried granite, of great strength. These dikes extend about 100 miles along the southern banks of the river. This had the effect, which has also been experienced in the Po and the Rhine, of raising the bed of the river, so that even when the river is low, its surface is being very much navigated; but at some later period it became unfit for navigation, like the Pelusian arm of the Nile. We do not know when nor under what circumstances this happened. It is however certain that on the northern side of the river, between the main dikes and the town of Kai-fong-foo, inundations occur, which are so extensive that they can only be traversed in several days. In these swampland grounds originates a river, called Wei-ho, which runs northward, and whose waters in the lower part of its course are used to form the Great Canal. It is very probable that this is the antecedent channel of the northern branch of the Hoang-ho.

In the reign of the last-mentioned monarch a large canal was made for the purpose of avoiding the too great accumulation of water in the Hoang-ho. This canal, which is situated in the province of Honan, and extends in a south-eastern direction to an arm of Lake Huang-tseu-hu (hu signifies lake). This canal is nearly 100 miles long, and it is stated that it had the effect of lowering the general surface of the river by about 70 feet. Large tracts of land which formerly were always wet, and water have been laid dry and rendered fit for cultivation. About 70 miles above its mouth the Hoang-ho receives a great supply of water by the channel by which Lake Huang-tseu-hu discharges its watercourse. This lake receives not only the waters brought from the Hoang-ho by the New Canal, but also those of the river Hsui-ho. The numerous rivers which unite with the Hsui-ho drain the extensive country which extends between the Hoang-ho and the Gie lowlands, and most of them rise in the most eastern offset of the Pe-ling range, which is known by the name of Mu-lung, and divides the province Hsing from Hupe. The two largest branches are called Yalu and Hsi-lung, and when the first named, which is far from the banks of the Lu-ho, is considered as the principal, the whole course of the river extends to 700 miles. The country drained by this river is flat, but appears to be less fertile than other portions of the plain. A short distance below the place where the two branches empty into the Hoang-ho are the two entrances of the Great Canal, which are graded by quays, built of large square pieces of granite sand stone and are nearly a mile wide. The Chinese who navigate the canal consider the passage of the two branches as the most remarkable monuments of the age, which frequently carries the barges for hundreds of miles. We have no account at all respecting the course of the Hoang-ho between the canal and the bouchure in the Hoang-hai or Yellow Sea.
During the long war consequent on the French revolution, and whilst this country was threatened with invasion, there was embodied in almost every county a mounted force of volunteers, with the title of Yeomanry Cavalry. It was subject to the same regulations, when on service, as the militia, and consisted of volunteers, of whom a large proportion were gentlemen or wealthy farmers; they were maintained for the most part, to their own expense; but they receive pay when in actual service, and there was some small allowance made by the crown towards the regimental expenses, such as the permanent pay of non-commissioned officers. They were commanded by the lord lieutenants of the county, who granted commissions to the subaltern officers.

The first act for embodying corps of volunteers was passed in the spring of 1794 (34 Geo. III., c. 31). It enacts that all persons who may during the war then raising volunteers not be employed under officers, holding commissions for that purpose from the king or from the lieutenants of counties, shall be entitled to receive the pay and shall be subject to the same discipline by courts martial, as the volunteer officers, as troops of the line, if on being called upon to dismount, or in the appearance of invasion they shall march out of their own counties or assemble within it to repel such invasion; or if they shall march at the command of the king or of the lieutenants of counties, their presence shall be reported by the justices of the peace within the county or the adjacent counties. The Act exempts volunteer officers from the militia; it gives power to the governors to billet the non-commissioned officers and domestic staffs on tavern keepers, and grants to commissioned officers and officers of the regular troops the benefit of Chelsea Hospital if they are disabled when on actual service.

In the year 1798 another Act was passed (38 Geo. III., c. 51), to facilitate the training of volunteer corps of avowed yeomanry. The object of this Act, though not in the body, 'yeomany cavalry,' It authorizes the billeting of the privates when called out to be trained, and it exempts from taxation the horses used in the service. After the short peace in 1802, the provisions of the preceding Act were dropped (42 Geo. III., c. 68), and the existence of the volunteer corps of cavalry (called by this Act for the first time 'yeomany cavalry') was revived or continued, without reference, as in the previous statutes, to the men's service.

Of late years, although many of these yeomanry regiments still exist, they are rather maintained for the purpose of amusement and good fellowship, than for any practical service; the necessary awkwardness of the men and their horses, and the expense of the maintenance of the yeomanry regiments, are causes of the latter service. In 1819, when a vast meeting was held at Manchester, it was dispersed by the yeomanry of that district with great, and, it may be said, unheard of success. In 1836, 338 troops of yeomanry cavalry, including 1165 officers and 18,120 men, at a cost of about 100,000L, per year to the nation. In 1838 the number of troops was reduced to 251, and the privates to 15,594. Between the years 1836 and 1838, the yeomanry were largely maintained out of the yeomanry corps was 128,000L, the greatest cost being in the years 1820, 1821, and 1822, when the annual average exceeded 192,000L.

YOGA. [The Sanscritical, yog, 'to join.' means the complete abstraction from all worldly objects, by which the Hindu ascetics hope to attain final emancipation from further migrations, and union with the universal spirit (Paramatma).] It chiefly consists in a continual meditation on the sacred monosyllable Om (the mystic name of the deity), profound contemplation of the divine excellence, and various acts of self-denial. The horrible tortures which the yogis commit on themselves are well known, and it is needless to repeat them here. It may however be necessary to mention that the Yoga is often practised for the purpose of obtaining the eight magical properties of power, viz. shrinking into a minute form, which is invisible (Prapti), attaining the power of a gigantic body (Mahamahā); or assuming levity (Laghūmā), rising along a sunbeam to the solar orb; or possessing unlimited reach of organs (Prapti), as touching the moon through the tip of a feather, and entering the moon with ease (Gaṇapammā), or sitting upon the sun and setting into the earth as easily as in water; dominion over all beings (Parapūtaka); faculty of changing the course of nature (Varanāsvāmā); ability to accomplish everything desired (Prākāramā). Consequently a Yoga, which has attained to have acquired such facts, is to vulgar apprehension a sorcerer, and is so represented in many a drama and popular tale. In the Purāṇas and other works, Yoga very often means magic, or the art of deluding.

YOGA is also the name of a branch of the Śāṅkhu's school of philosophy, for an account of which see SANSKRIT LANGUAGE AND LITERATURE.

YONNE, a department of central France, bounded on the north-east by the department of Aube, on the east by the department of Côte d'Or, on the south by that of Nièvre, on the west by that of Nièvre and the Marne, and on the north-west by that of Seine et Marne. The department lies between 47° 20' and 48° 24' N. lat., and between 2° 55' and 4° 20' E. long. The form of the department is irregular; its greatest length is 131 miles, and its greatest breadth, 92 miles. It consists of a heterogeneous province, lying between the river of the Yonne, which was called the bank of the Yonne at Villenевre-la-Guïard, above Montereau-fault-Yonne, in the north-west, to the junction of the three departments of Yonne, Nièvre, and Côte d'Or; in the south-east, 62 miles; the greatest breadth at right angles to the border of Nièvre, 38 miles; the border of Aube near Neuvy to the junction of the three departments of Yonne, Nièvre, and Loiret, 53 miles. The area of the department is estimated at 2,621 square miles, being considerably larger than the average of the French departements.

The population in 1826 was 342,116; in 1831, 392,487; and in 1836, 355,237, showing an increase in the last five years of 2700, or about 0.8 per cent., and giving 326 inhabitants to a square mile. In amount of population it is considerably below the average of the departments, and in density of population still further below the average. Auxerre, the capital, is 88 miles in a direct line south-east from the barrier of Paris, or 100 miles by the road to Avallon. The department has no mountains; but it has in many parts an undulating surface; the highest ground is toward the south-western corner, where the low hills which separate this part of the department from the rest of the country. The country about Avallon is comprehended in the granite district of Morvan; the rest of the department south-east of a line drawn from Côte on the Loire, by Auxerre, toward Troyes, is occupied by the oolitic and other formations which intervene between the cretaceous and the new red-sandstone groups, and the part of the department which is north-west of such line is occupied by the cretaceous formations which surround the chalk-basin of the town of Tonnerre. Lime-flags and marls, and stone suitable for lithography are quarried; and gunflints, and red and yellow ochre, are procured. A mine of lead and silver was worked in the middle ages near Avallon: the working was resumed in the last century, but was soon abandoned. The department belongs almost entirely to the basin of the Seine. Some parts along the western border are drained by the Loing; and by the Ouanne, the Clery, the Bes, and the Lomnain, all of them small affluents of the Yonne; the central and eastern parts are drained by the Yonne; by the Cure, the Serein, the Armançon, the Tholon, the Yvin, and the Vannes, feeders of the Yonne; and by the Voisin (with its affluent the Cousin), and the Armançon, feeders respectively of the Cure and the Armançon.

The Loing and its feeder the Ouanne rise in the south-west part of the department, and have a north-western course into the adjacent department of Loiret, in which...

[Digitized by Google]
their junction takes place. The other feeders of the Loing have only their sources and the upper part of their course in this department.

The Yonne rises in the department of Nièvre, near Château-Chinon; and flows north-north-west by Château-Chinon, Morceaux, Tanay, and Clamecy, into the department of Yonne. Its course is through this department, and the whole still north-north-west: it passes Coulanges, Châtel-le-Censoy, Mailly-le-Château, Cravant (just above which it receives the Cure on the right bank), Auxerre; Joigny (below the right bank); and at the latter town it receives the Souron and the Armançon, both on the right bank); and just below Joigny it receives the Tholon and Yrin, both on the left bank. St. Julien, Villeneuve-la-Regn, Sens (near which it receives the Vannes on the right bank, Pont-sur-Yonne, and Villemain). Below Villeneuve-la-Regn it enters the department and enters that of Seine et Marne, through which it flows a short distance west-north-west to Monte-
neuf-fault-Yonne, where it unites with the Seine. Its whole course may be estimated at about 150 miles, namely, about 80 in that of Yonne, and 6 in that of Seine et Marne. The river is employed for floating timber from near its source: at Clamecy the timber is formed into trains or rafts, and floated down to Auxerre. At Auxerre the navigation commences, and extends about 80 miles, most of which is in this department. Its course may be estimated at above 50 miles, about half of which is in this half. It is used for floating timber. The Voisan, which joins the Cure, and its feeder the Chantereine, enters the department of Côte d'Or, on the north-east; the length of the Voisan is about 30 miles, and of the Cousin about 14. The Serein rises in the department of Côte d'Or, and flows north-east into the department of Yonne, where its course is at first in the same direction. Afterwards it bends more towards the north, it passes Montréal, L'Isle, Noyers, Chablis, Ligny-le-Châtel, and Seignelay, and falls into the Yonne. Its whole course is more than 80 miles, about two-thirds of it in this department.

The Armançon rises in the department of Côte d'Or, and flows north-north-west by Sens into the department of Yonne, through which it flows north-west by Nuits, Ravières, Anc-le-Franc, Tanlay, Tonnerre, Épineuil, and Dammarçon; then westward by St. Florentin and Gcize to the Yonne. The whole course may be estimated at about 92 miles, about 36 in the department of Côte d'Or, and 56 in that of Yonne. The Armançon belongs chiefly to the department of Aube: its length is about 27 miles, one of 7 of which is in the department of Yonne. Both the Armançon and its feeders, including the Armaise, are used for floating timber; below the junction of the Armançon the timber is formed into rafts or trains. The Tholon is 17 miles long, the Yrin 17 miles, and the Yonne about 28: the last rises in the department of Aube, and flows westward, passing Villeneuve-l'Archevêque, Poisy, and Chilly; it is used, as well as the Vrin, for floating timber.

M. Millin (Voyage dans les Dép. du Midi de la France, etc.) has described the manner of sending timber down these streams:—"One is particularly pleased to see pass with the rapidity of a bird's flight those long and narrow rafts called "trains," which convey to Paris a considerable part of the wood necessary for the consumption of that city. At their outbreak the logs are formed into trains, and the persons employed distinguish by the mark those which belong to each proprietor. The logs, tied together with twigs, are placed on hollow vessels or floats ranged at intervals, and form "trains," each guided by three men, to Paris. These boats skillfully follow the windings of the banks, avoid the shoals, with which they are well acquainted, and exhibit their quicksight and all their skill in steering the bridges, through which they pass as quickly as possible: the head of the train is scarcely seen, when in an instant it is already far off. As soon as the train arrives at the wharfs at Paris, men plunge into the water to bring the logs up to the middle, pull it to pieces, and load it on the wharfs. However, a sudden rising of the waters of the Loing sometimes occasions terrible disasters; sometimes, as in a forgetful moment the frat construction is allowed to get out of its course, is stopped, and the whole stream which are picked up by a crowd of people, but without the proprietor being able to recover more than a very few parts."

There are two navigable canals in the department, one from the provinces through which they pass. The Canal de Bourgogne connects the river system of the Seine at Châtillon-sur-Marné to the Yonne at Joigny. The Armançon is taken up the valley of the Armançon chiefly on the north-east bank of that river, then up the valley of the Brenne, a feeder of the Armançon, and, crossing the Seine, which separate the basin of the Seine from that of the Yonne, to the valley of the Yonne. At Châtillon, near the Seine at St. Jean-de-Losne, the Yonne is joined by the Canal de Bourgogne. At this point all the vessels which pass by the Yonne officially stated at 91,832 mètres (about 57 miles) on the south side of the descent from the summit-level to the level of the basin is of 311 mètres (about 1020 feet) long, and was projected by J. IV., but was not commenced until 1776; and if finished which we have no certain information has been com-
pleted only within a very few years. The Canal de Bourgogne the descent to the commence the navigation on the Yonne at Auxerre, a considerable part of the canal above Auxerre being comprehended in it. The route of the canal which belongs to this department, includes all the incorporated part of the course of the Yonne officially stated at 33 miles. What progress has been made in the works of this canal we have no means of judging. The descent from the summit-level towards the Yonne is accomplished by 26 locks; that towards the Yonne by 7 locks.

The number of Routes Royales, or government roads January 1, 1859, was six, having an aggregate length of 329 miles, of which some 50 miles are in courses which is in bad repair, and 200 miles unfinished. The principal roads are those from Paris to Lyon by Auxerre, and both of which are of the first class. The road by Auxerre which is the principal, enters the department on the east side near Villeneuve-la-Regn, and follows the right of the Yonne, passing by Pont-sur-Yonne, where it receives the Yonne from the left bank to the right: then by Sens-la-Regn, Joigny, where it receives the Yonne from the left bank, Auxerre, where it crosses the town at the time, and by Vernois into the department of Côte d'Or. It formerly passed through Vallon, but a short cut has been made, by which this town is avoided. The road through Dijon branches off to the left from the road to Auxerre at Joigny, and follows the valley of the Yonne through the forest, made of the Aube, Damanville, Lour-nay, Tonnerre, Anc-le-Francois, and Nuits, into the department of Côte d'Or.

Roads lead from Auxerre west-north-west by Toucy to Fargeau to Bone, which runs through the department of Nièvre to Clamecy, Nevers, and Montils; north-north-east by St. Florentin and Nevers to Tonnerre to Chalons-sur-Marne. A road leads from Sen-sur-Yonne, east to Poissy and Villeneuve-l'Archevêque; from there the road is stopped, and the po-
In its means of communication this department was rated by Dupin, in 1827, to be on the whole considerably below the average of France; but its pre-emminence was rather in its means of water-communication than in its roads, in which, in proportion to its area, it was rather below the average.

The area of the department comprehends in round numbers about 1,900,000 acres; of which about five-eighths, r from 1,100,000 to 1,150,000 acres are under the plough, the produce in wheat is considerably below the average of France; maize is not grown at all, and buckwheat is grown very little; but in others of Le-Meuse, one rye, maize, r wheat and r mixed, and especially in barley, the department far exceeds the average. The cultivation of potatoes is less than the average of the departments.

The whole production in grain is greater than the consumption of the department, and above 1,000 quarters of oats and 700 quarters of broad-corn are exported to other departments.

The grass lands amount to nearly 80,000 acres, the common lands and open pastures to 45,000. The department is singularly rich in iron-works; trade is carried on in firewood, charcoal, and especially in the number of sheeps. In the number of horses it is also below the average, but not so far below as the number either of horned cattle or sheep.

The vineyards consist of 60,000 acres, and in the extent of these and in the quantity of wine produced the department very far exceeds the average; wine is in great plenty production of the department. The growth, 1 proportion to the number of inhabitants, was estimated in 1827; of which 3,000 acres were wine is known, and another 3,000 acres were wine is known. There are three wine-fairs in the year; one in Yonne, another in Nievre, and the third in Yonne.

A great quantity is sent to Paris and to the departments lower down the Seine. The wines are known by the general designation of 'vins de Bellev Bourgogne,' or 'Lower Burgundy wines.' Some of them are in high repute; the red wines of L'Isle, over, are exported, and Cognac, and Auxerre are of the first class; and those of Avize, Clairon, Boivin, Migrenne, Judas, Pied-de-Rat, L'Isle, Quétard, Epinay, Irancy, and Coulanges-la-Vineuse, of the second class. Of the white wines those of Coulanges are seven years old, and sold to the Egyptian government, which, in 1822, purchased 500,000 cases of these wines. They are produced annually in the department in value of £150,000.

In the department of Yonne, there is also a considerable trade in wines; and that in the trade in wines is the most important, and that in the trade in wool, for it is the department where the largest quantity of wool is produced. The trade in wool is carried on in the department in the manufacture of cloth, and in the manufacture of woollen goods, and in the manufacture of cloth, and in the manufacture of woolen goods, and in the manufacture of woollen goods, and in the manufacture of woollen goods.

The population of the department in 1826 was 1,575,183; and in 1831, 1,600,000. The principal towns are

Avallon, population 17,100; a town of considerable importance, situated on the right bank of the Yonne, and near the Cité; Charlet-le-Censoy on the Yonne; Thionville, population 8,500; a town of importance, situated on the left bank of the Yonne, and near the Cité.

The department is divided into five arrondissements as follows:

The arrondissement of Auxerre are the following towns:

Avallon, population in 1826, 12,348; in 1831, 14,339 (of whom 10,098 were in the town itself); in 1836, 15,578, on the Yonne [Auxerre].

Craney, Cravant, St. Brix, Bois-le-Roi, and Bréville, population 17,100 for the commune, Mailly-le-Chétel and Coulanges-sur-Yonne, on the Yonne, served by a mail coach; Auxerre, population 17,100 for the town, or 28,800 for the whole commune, Chablis, population 3,000 for the town, or 5,000 for the whole commune.

Avallon, population 17,100 for the town, or 28,800 for the whole commune, St. Florentin, population 2,396 for the town, or 4,042 for the whole commune, on the Armanne; Coulanges-la-Vineuse, Charentenay, Toucy, Ouson, and St. Sauveur, in that part of the arrondissement which lies west of the Yonne. The latter is known for the wines produced in the neighbourhood. Cravant has some historical interest as the scene of a severe battle in 1657. During the attempt of the English under Henry V. and VI. to conquer France, the lordship of St. Brix or St. Brix belonged to Louvois, the well-known minister of Louis XIV.

The third crusade, Philippe Auguste, of France, and Richard Cœur-de-Lion, of England, united their forces at Vezelay, to the number of 100,000 warriors. It was occupied for some time by the Huguenots in the religious wars of the sixteenth century: Theodore Beza was born in the town.
The townspeople carry on trade in corn and wood: there are twelve yearly fairs for corn, and wool. There are mineral waters and mineral springs near the town. Châtelet-le-Censuy has some ironworks. Montréal had an ancient castle, which was for some time the residence of Queen Brunehaut, and, as it is said, of Francis or Francis I. The neighbourhood produces some fine wool. There are harvests in the year. Joux-la-Ville has four yearly fairs for corn, wine, cattle, and staves.

In the arrondissement of Joigny are the following towns:—Joigny, population in 1826, 5283; in 1831, 4760 for the whole commune; and in 1836, 5037 for the whole commune, 7544 on the Yonne; St. Julien and Villeneuve-le-Roy, population 3784 for the town, or 4966 for the whole commune, on the Yonne; Briçon, population 2464 for the town, or 2966 for the whole commune, near the Armançon; St. Mars, population 1370 for the town, or 2172 for the whole commune, and Bleneau, on the Loing; St. Benoist and Charny, on the Ouanne; Tonnerre, on a small affluent of the same river; and Dinxmont and Cerisiers, in the country on the right bank of the Yonne. Joigny was in the Latin of the middle ages called Jovinsacum; and its origin and name are said by some to be derived from JVovius, a commander of the Roman forces in Gaul in the reigns of Julian, Jovian, and Valentinian I. It had a strong castle in the town, and was the capital of a county. The town stands on the slope of a hill, rising from the right bank of the Yonne, over which there is a handsome stone bridge; along the bank of the river on each side of the bridge extends a broad and elevated quay, fronting which is a long and magnificent cavalry barrack. The streets are very steep, narrow, and winding, and are lined for the most part with wretched houses, among which are mingled a few old and very handsome constructions. In the upper part of the town is a fine château or castle, the windows and terraces of which command a beautiful prospect. Near it is the church, the fine vaulted roof of which, although mutilated, is worthy of notice. The town has two fairsbourgs or fairs, one is held at the foot of the bridge, on the opposite side of the Yonne. The town has some subordinate judicial and fiscal offices, two hospitals, a communal school, a large market-place, and a theatre. The townspeople trade in oak-bark, wood, charcoal, casks, hoops, wine, which is produced in the neighbourhood, good quality, brandy, and vinager; there are brandy-distilleries, tan-yards, and tile-yards; whitening is made. There are four yearly fairs for corn, cattle, charcoal, casks, and hoops. St. Julien, distinguished by St. Julien-le-Cap, on the left bank of the Yonne, has manufactures of polished steel articles and jewellery, and of coarse woolen cloth; there are some tan-yards and a bark or tan mill. There are four yearly fairs for kitchen and household utensils. The wine of the near parts of St. Julien is known, and it is held in good repute. Villeneuve-le-Roy, or Villeneuve-sur-Yonne, is on the right bank of the river, over which there is an old stone bridge. The principal street of the town is straight and handsome, with a gate and an avenue of trees at each end; the church is near the centre of the main street, and has an elegant front, with a handsome door on each side. Coarse woolen cloth and leather, and a confection of grapes, which is well esteemed at Paris, are made; and trade is carried on in wine, wood, and charcoal. There are four yearly fairs. Bréon, or Brinon, sometimes distinguished by the epithet 'l'Archevêque,' is a well laid out, well-built, handsome town. The townspeople manufacture woollen yarn, coarse woolen cloths, and leather, and carry on considerable trade in firewood, which is floated down the Armançon, and then by the Yonne and the Seine to Paris, charcoal, corn, and linen; there are six yearly fairs. At St. Fargeau and Bleneau trade in wood is carried on. St. Fargeau has seven yearly fairs. Bleneau was the scene of a battle in which Condé and the church of the minority of Louis XIV. Dixmont has two fairs in the year, for cattle, wool, and hemp.

In the arrondissement of Sens are the following towns:—Sens, population in 1826, 6065; in 1831, 5567 for the town; and in 1836, 6056; on the Yonne [Sens]; Pont-sur-Yonne, and Villeneuve-la-Gaizard, population 1794, on the Yonne; Chercy, on the Lure; Stery, La Chapelle-sur-Sereine, Sargines or Sargines, Vauxins, and Thirouville, in the country on the right bank of the Yonne; and Villeneuve-l'Archevêque, popula-

The town suffered severely in 1816 from a waterspout, which destroyed persons and did great damage to houses and property. There are three yearly fairs. There are public buildings in the year. There is a paper-mill at Villeneuve-la-Gaizard, and there are three yearly fairs. The town manufactures coarse woollen cloth, a tan-yard, and tan and tanning materials. Les Soyez is a suburb; it is a river stream whichweet the Vannes and is used for floating wood.

In the arrondissement of Tonnerre are the following towns:—Tonnerre, population in 1826, 3600; in 1831, 3773 for the whole commune; in 1836, 4293; Tanlal, Ancy-le-Francois, Neuvy-l'Arcb.eveque, the Pont-sur-Yonne, the Arme, and Noyers on the Serein. Tonnerre is on a slope of a hill, and is surrounded by woods. The hill, on which there is a stone bridge, and in a district which produces excellent wine. The Canal de Bourgogne passes near the town, which is well laid out and well built. It is a town of houses of stone. The pariah church is in a remarkable situation, and is surrounded by a wood. A town founded in the latter part of the thirteenth century by a princess of the ducal house of Bourgogne. The church of the hospital is remarkable for its size, and for the bold architecture of its vaulting, and the remarkable forms of its columns. The church was destroyed by fire, and is a communual college, a theatre, and a fine pape walk. There are a saw-mill, saw-mills, timber-yards, saw-mill shops, and corn-mills; paper-hangings and artistic implements are manufactured; and trade is carried on. There are three yearly fairs. There are some administrative and civil government offices, and a subordinate court of justice. Courses of instruction are given in geometry and mechanical sciences. In one of the suburbs is a spring of water copious that it forms several small streams close to a source. Tonnerre was nearly destroyed in the wars of France under Edward III., and in the civil wars of the Bourguignons and the Armagnacs. It was the scene of many engagements and battles. It was the residence of the Chevalier d'Eon de Beaumont, who, after distinguishing himself as a diplomatist and a soldier, was obliged, by an order of the French king, for some erroneous reason, to assume the garb of a female. Here are described the story of the famous tradesman. At some trades and in corn and wood, and there are six yearly fairs. Noyers is in a valley inclosed by hills covered with vinyards. It has an hospital. The townspeople manufacture woollen yarn, coarse woollen cloths, and leather, and carry on considerable trade in firewood, which is floated down the Armançon, and then by the Yonne and the Seine to Paris, charcoal, corn, and linen; there are six yearly fairs. At St. Fargeau and Bleneau trade in wood is carried on. At St. Fargeau has seven yearly fairs. Bleneau was the scene of a battle in which Condé and the church of the minority of Louis XIV. Dixmont has two fairs in the year, for cattle, wool, and hemp.

The population, when not otherwise described, is of the whole commune, and from the census of 1836.

The department forms the archiepiscopal see of Sens and Auxerre, and is the seat of the bishopric. The bishops are the bishops of Troyes, Nevers, and Moulins. The department is in the jurisdiction of the Cour Royale and the Université de Paris, and is included in the second military division, the head-quarters of which is at Joinville.
aspect of education it is above the average of France. Of a young men enrolled in the military census of 1828-6,
the number of the young men in the military service was the average of France being less than 39 in every 100.
In the earliest historical period the greater part of the depart-ment was included in the territories of the Senones and the Emomios, but the eastern part about Tomerre belonged to the Lingones or the Aisadisci and Aisiovesc, Strabo, the southern part about Avalon to the Aedui, or Hedu, (Edes or Adesom, Hede, Aedes, Ploenest), These were Celtic nations, and the Senones joined the Romans of Edward V. and his two sons, Henry V., and Henry VI., were descended only from John of Gaunt, duke of Lancaster, the fourth son of Edward III. The son of the earl of Cambridge and of Anne Mortimer was Richard Plantagenet, who became the third duke of York, in 1460, and the last of the line of Edward's eldest son, Edward, who ascended the throne as Edward IV. in March the following year. After the death of Edward V. and his brother, some time in 1483, the representation of Edward IV. rested in his eldest daughter, Princess Elizabeth, who married James IV. of Scotland, and was the mother of Henry VIII., and also, through her eldest daughter Margaret, who married James IV. of Scotland, the ancestor of James I., who, in virtue of that descent, succeeded to the throne of England, on the failure of the eldest son of Henry VIII., and his two sons, Henry, who was descended from Elizabeth, the eldest daughter of James I., the line of his son Charles (with the exception only of Mary and Anne, the two daughters of James II., neither of whom left any issue) having been expelled from the throne at the Revolution of 1688.

Since the time of Edward IV. the title of duke of York has been borne by Richard Plantagenet, the second son of that king; upon whom it was conferred in 1474, and who was raised by his elder brother, Edward V., to the dukedom of York, in 1483; by Henry Tudor, second son of Henry VI., who was created duke of York in 1491, and who became prince of Wales on the death of his eldest brother Arthur in 1503, and ascended the throne as Henry VIII. in 1503; by Charles Stuart, second son of James I., upon whom it was conferred in 1604, and who became duke of Cornwall on the death of his eldest brother Henry in 1612, was created prince of Wales in 1616, and ascended the throne as Charles I. in 1625; by James Stuart, second son of Charles I., upon whom it was conferred in 1651, and who was created duke of York and Albany in 1674, and died without issue in 1702, and by James Stuart, the eldest son of Henry, who was created duke of York and Albany in 1716, and died without issue in 1717; and by Frederick, next brother of George IV., who was created duke of York and Albany in 1784, and died without issue in 1827.

The capital of the most extensive county in England, and a place of distinction from the earliest period of authentic British history, is situated on the banks of the Severn, or Wye, which flows through the midst of it, and receiving in its course nearly all the waters of Yorkshire, forms, in conjunction with the Trent, the estuary of the Humber. According to the "Trigonometrical Survey," by Mudge, the latitude of the Minister, which stands in the north-west corner of the city, is 53 37' 39" N., and the longitude 1° 2' 31" W., or the 144th meridian.

York, being originally a town of the Huggerists, a people of Celtic origin, inhabiting the country extending northward from the Mersey and the Humber to the Firth of Solway and the Tyne, and descended from the British town of York, there is no doubt that it was a collection of huts surrounded by a trench and the trees which had been cut down for the building of the town. The site of the town was the seventh century. The most probable remains of a Roman station on the site of York, near the confluence of the Yarli and the River Nidda, is a Roman station on the site of York, near the confluence of the Yarli and the River Nidda, or near the confluence of the river Ems and the North Sea. It was a Roman station on the site of York, near the confluence of the Yarli and the River Nidda, or near the confluence of the river Ems and the North Sea.
subdued the whole country of the Brigantes; its original Celtic appellation being retained in the Latinized form of Eboracum. It appears to have very soon become the principal Roman station of the north, and even of the whole province of Britain. Whether it was a colony or a municipium has been a subject of dispute. In the one description it is called a colony; in the other, a municipium. The head-quarters of the sixth legion from the time of its arrival in Britain in the reign of Hadrian, till the departure of the Romans from the island. The present name, which came over with the emperor Constantine, had previously been stationed here, and, of course, continued here after its incorporation with the sixth. From the time of Septimius Severus, if not earlier, it was the residence of the emperors when they visited the province, and, in their absence, of the imperial legates. Here the emperors Septimius Severus and Constantius Chlorus died; and here, according to common belief, Constantine the Great was born. But this belief rests upon very insufficient evidence. For its pre-eminence among the Roman stations in Britain, Eboracum was indebted, in a great measure, to its situation by the banks of a navigable river, in the midst of a remarkably extensive and very fertile plain, in the heart of the large district which lay between that part of the province of which the Romans had absolute undisturbed possession, and which they never could subdue, with the fierce hordes of which they were compelled to wage unceasing and doubtful warfare. Similar circumstances contributed to maintain the distinction which York enjoyed during many centuries.

One of the angle towers and a portion of the wall of Eboracum attached to it, are to this day remaining in an extraordinary state of preservation. In a recent removal of a considerable part of the more modern wall and rampart, much larger portion of the Roman wall, connected with the same angle-tower, but in another direction, with remains of two wall-towers, and the foundations of one of the gates of the station, were found buried within the ramparts; and excavations at various times and in different parts of the present city have discovered many indubitable remains of the fortifications of Eboracum, on three of its sides, that the conclusion appears to be fully warranted that this important station was of a rectangular form, corresponding very nearly with the plan of a Polybarium, occupying a space of about one-third of a mile by about 550, inclosed by a wall and a rampart mound on the inner side of the wall, and a fosse without; with four angle towers, and a series of minor towers or turrets, and having seven gates or principal entrances, from each position, and meeting the neighbouring stations mentioned in the "Itinerary of Antonine. Indications of extensive suburbs, especially on the south-west and north-west exist in the numerous and interesting remains of fragments, such as tombs, coffins, urns, tiles, and villas which from time to time, and especially in late years, have been brought to light. Numberless tiles, bearing the impress of the sixth and ninth legions, fragments of Samian ware, inscriptions, and coins from the age of Julius Caesar to that of Constantine and his family, concur with the notices of ancient geographers and historians to identify the situation of modern York with that of ancient Eboracum.

The interval between the final departure of the Romans from Britain, and the arrival of the Saxons in the southern parts of the island, which had long been harrassed by their fleets, was very short; but more than a century appears to have elapsed before the foundation of any Saxon kingdom north of the Humber was laid. During this long period the Saxons had the whole of the northern half of the island to themselves. The inhabitants were no doubt chiefly descendents of the ancient Brigantes, who, retaining their ancient language, though their ancestors, as Tacitus tells us, had been taught to speak the Latin tongue, were the original stock of the city, with a very slight variation, and the addition of a British term indicating the increased dignity and strength of the place. For it is most probable that it was during this period, and not, as is generally supposed, prior to the invasion of the Romans, that the city received the appellation of Caer Ebrauch. Though it lost the pre-eminence it had so long maintained, as the different Anglo-Saxon kingdoms rose and flourished, yet it was unquestionably the chief city of the north; an important bulwark against the incursions of the Picts, from which there is reason to believe it suffered greatly, if not holpen, at the time discovered here; but it is not improbable that one of the remains generally regarded as Roman may belong to this period.

In the authentic and valuable record the "Saxon Chronicle," no mention of an Anglo-Saxon kingdom north of the Humber occurs till the year 577, when Ida, the head of a body of Angles, took possession of Beornic, one of the two great divisions of the country, and settled in the neighbourhood of the Tees. Thirteen years afterwards, the other division between the Tees and the Humber, called Deira, or Deir, was seized by Aella, another Anglian chief. These kingdoms were soon united, and generally considered as forming a kingdom under the name of Northumbria, of which York was certainly the capital. By Tewold Beda and other Anglo-Saxon writers the Roman name of the city is retained. On some Anglo-Danish coins it is corruptly called Braeth. In the "Saxon Chronicle" and in Anglo-Saxon records, it appears generally in the form of Ewic. During the Anglo-Saxon and Danish period, it is even to the end of the reign of Henry III, at which time the coin struck at York. The orthography varied, and in every form its relation to the original Latin was easily traced. It is known in one of its forms, Ewreic, to the present day.

The historical notices of York from the foundation of the kingdom of Northumbria to the Roman conquest is but scanty, but they are continued to be a place of considerable importance, as the principal royal residence. At York, Edwin was not only king of Northumbria, but the fifth he held his court. Here, under the lofty walls of a city which says Alcuin, had erected the first metropolitan church. Here many kings of Northumbria were consecrated and many were buried here; and some, abdicating, finished their lives in the peaceful retreat of the cloister. We have discovered many evidences to employ a considerable force in order to make master of this bulwark of the north. Athelstan, who united Northumbria to his dominions, deemed it prudent to demolish the castle of York. Edgar the fifth sole king of England, held his court here, and this city. Siward the Dane, who was earl of Northumberland in the reign of Edward the Confessor, built a church at York, dedicated to the royal Danish saint Olaf, preparatory to his intended foundation of a church at the time of the Conquest. Edgar the fifth held his council here a few months after his departure, and set out for the north. Very few Saxon or Danish relics have been discovered at York. An interesting portion of the Saxon church erected by Paulinus, or by Albert, has been recently brought to light beneath the choir of the present cathedral; and fragments of crosses, or commemorative plaques and some coffins, both of stone and wood, belonging to the Saxon period, have occasionally been found. The Danish relics have at various times been discovered, a large hoard of sceats, a coin peculiar to Northumbria amounting to more than 5000, has been lately discovered and probably struck at York, the only place in the Anglo-Saxon kingdom of Northumbria at which a mint could be established. The Danish章the possession of a large and beautifully carved iron horse Danish relic, presented to the church by Ulphus, a Danish chief and friend of Caute, when he colonized it with his people, but which was the original treasure of the church. Although William was crowned in London by Alun archbishop of York, the claims of the Conqueror were not yet long while strenuously resisted in the north, where William nobles espoused the cause of Edgar. Harold. As soon as affairs in the south were pacified, William took possession of York, built or repaired the castle in it, and strongly garrisoned it with Norman soldiers. Notwithstanding this, Edgar Atheling escaped to York, and was acknowledged king. The church,
ored by a powerful battery of guns and mortars, a considerable number of besiegers became wounded or killed by shell, and many of the garrison were killed or took refuge in the tower. The town was soon reduced to the state of a fortress, and the garrison was forced to surrender.

By the end of 1665, the town had fallen into ruins. The bridge over the river was destroyed, and the surrounding countryside was desolate. The town was abandoned and left to the ravages of time.

In 1668, the town was finally captured by the English and became a garrison town for the Commonwealth. It was garrisoned by a large force of soldiers, who built fortifications around the town to prevent it from being recaptured by the Royalists.

The town was eventually rebuilt and became a thriving center of commerce and industry. It was known for its woolen industry and its shipbuilding yards. It remained a garrison town until the end of the 18th century, when it was finally abandoned and left to the ravages of time.
gates were again defiled by a spectacle worthy only of an age of the grossest barbarism.

Among the interesting relics of Eboracum, or of York under the Romans, are remains or memorials of Roman temples; but although the Britons, as well as the Romans, had undoubtedly inhabited the site of Chester, so faithful was the departure of the latter, no trace of any sacred Christian edifice of Roman or of British times has been discovered. That churches had been built in many parts of the empire previous to the establishment of Christianity by Constantine is certain, and is by Eusebius; and there is no reason to suppose that a station so important as that of Eboracum would be destitute of them. Whatever edifices of this nature may have existed at York before or after the departure of the Romans, they were probably destroyed by the Saxons, when they founded the kingdoms of the Octarchy were universally pagans. Such they continued to be till about the end of the sixth century, when Ethelbert, the Saxon king of Kent, was converted to the Christian faith by the preaching of the saint Augustine, Edwin, the fifth Saxon king of Northumbria, and a native, it is said, of York, had married Ethelburga, the daughter of Ethelbert, and, through her influence and the zeal of Paulinus, a companion of Augustine, became a convert, and, as he became a heathen, a considerable number of the nobles of his kingdom, was baptized by Paulinus on Easter-day, in the year 627, at York, in the church of St. Peter, which, says Beda, he had hastily constructed while he was a heathen, and prepared to receive baptism. Soon afterwards, by the advice and with the aid of Paulinus, to whom he had given York as his episcopal see, the king made preparations for building a larger and a nobler church, in the midst of which the oratory, formerly consecrated and in which he had been baptized, might be included. He laid the foundation and began to raise the edifice; but before the walls were completed he was slain. The work was finished by his successor Oswald; but when he had also fallen, and Paulinus had returned to Rome (it is said that Paulinus had received the pallium from Rome, and been elevated to the rank of archbishop of York) he had been compelled to retire with Ethelburga to Kent, the church was wholly neglected, and burned.

From this sad state the celebrated bishop St. Wilfrid, in the beginning of the seventh century, restored it, adding greatly to its splendour by the assistance of artists whom he had brought with him from the Continent. About fifty years after this, in the year 741, the edifice was destroyed or greatly injured by fire. In the episcopate of the celebrated Albert, who was elected to the see of York in the year 707, a new church was begun, finished, and dedicated; from the description of which, by Alcuin, the learned pupil and friend of Albert, in his De Pontifici, Sacrae Ecclesiae we are warranted in concluding that it was one of the most magnificent of the Anglo-Saxon churches. A small but very interesting portion of this church, comprising a part of the earlier church built by Edwin, has been recently brought to light during the excavation of the present choir, after the calamitous fire in February, 1825. Attached to the church was an episcopal monastery, in the school of which Archbishop Egbert, the predecessor of Albert, taught, and which he enriched with a noble library collected by him with great labour and expense. This celebrated library is supposed to have perished in the conflagration that destroyed a great part of the city and the cathedral in the beginning of the reign of William the Conqueror.

Archbishop Thomas, who was appointed to the see by William, in the year 1070, finding the church 'thus spoiled, rebuilt it,' according to the testimony of his friend Hugo the Precentor, 'from the foundation, and adorned and enriched with gold and silver.' From remounting the crypt, discovered in the recent excavation and preserved beneath the floor of the present choir, a good idea may be formed of the grandeur and beauty by which the entire edifice must have been distinguished. It appears to have been greatly injured in part perhaps destroyed by fire in the year 1137; after which it is commonly believed to have been rebuilt by Archbishop Roger. But there is sufficient evidence to show that it did not then require repair, and that the repairs and alterations were confined to repairs, alterations, and additions. It cannot be ascertained what was the state of the fabric in the beginning of the thirteenth century, when Walter Greu was consecrated to the archbishopric; it is certain however that the present south transept was begun by him about the year 1220, and it was probably finished during his episcopate, about the year 1241. The rebuilding of the north transept is thought to have been begun by the same prelate, and not completed till several years after his death. There are no documents in existence relating to the building of the chapter-house, but it is conjectured with great probability that the magnificent structure of stone was completed by the end of the thirteenth century; the two peculiar features were built in the year 1284, but that the west front was not completed before the year 1340. The present nave was begun in the year 1291, in the episcopate of John de Ro- main, but not finished till the year 1360, in the episcopate of Thoma the sofas. The south transept was not completed before the year 1472. About that time the central or lantern tower was finished; and very shortly afterwards the upper storey of the north-west tower, the south-western tower having been finished probably two or three years earlier.

This magnificent cathedral is cruciform, measuring a length from base to base of buttresses east and west, 519 feet, and from base to base of the transepts 26 feet. The internal breadth east and west is 465 feet, the transepts 222 ft. 6 in. The broad aisles have side aisles, two transepts with side aisles, a choir on side aisles, a Lady-Chapel, a large central tower, two lower towers, and a chapter-house with its vestibule. Outside the nave is attached a transept, and a western tower is 93 feet, of the choir 101 feet, of the central tower externally about 198 feet, internally 182 ft. 6 in. The height of the western towers is about 201 feet to the top of the pinnacles, 178 ft. 3 in. to the top of the battlement. In the chapels and paternosters attached in the nave, the length of the pinnacles is 124 ft. 19 in. The arches being angular in 60 ft. 6 in., and the height of the central base from the floor 62 ft. 2 in. The roof is supported by no pillar.

It is a remarkable circumstance in the history of the magnificent edifice that two of the principal portions of it have within the space of twelve years been destroyed by fire: the middle aisle of the choir by the fanatic monastic Jonathan Martin, in the year 1829; and the south-western bell-tower with its fine peal of bells, in the middle of the same year; the remainder, through carelessness in 1840. In both occasions the grand central tower presented to flames from spreading to the transepts.

The palace of the archbishop was antiently on the south side of the cathedral. Archbishop Roger it is said, rebuilt it in the latter end of the twelfth century, and a small portion of his work is still remaining, as the base of the palace, of a later date. This elegant building has been long an unsightly ruin, was repaired in the time of the deans and chapter. Near it is the new deanery, the residence of the dean, which was on the south side of the Minster, having lately been taken down. A house for the residence of the canons residuary has also been erected on the north side of the Minster in the site of one of the ancient archiepiscopal palaces.

The monastic institution appears to have been introduced into Britain by Augustine at the end of the sixth century, when a monastery was established at Canterbury by the royal convert. About fifty years afterward several monasteries were founded in the kingdom of Northumbria; but no establishment of regular monks is known to have existed at York prior to the Norman conquest. Since before the reign of King Stephen, on the 1st of July, in the island, laid the foundation of a monastery near the walls of York; but the building did not advance beyond the erection of the church; and the foundation was laid anew, and a great part of the monastery completed, by William the Conqueror, according to that which H. of Grace, the Blessed Virgin Mary. About the end of the thirteenth century the church and a great part of the monastery were rebuilt; but several portions of the ancient structure still remain. During the government of the third abbot Gruff, Archbishop Egbert, desirous of adopting the Cistercian rule, secured and founded the abbey of Fountains near Ripon. William Thornton, the last abbot, surrendered to the king in 1540, the work of the nave was finished, including the abbot, prior, and sub-prior, and one sub-priest. The clear value was reckoned to be 1060L. out of the
Till the passing of this act the jurisdiction of the corporation was not restricted within the proper bounds of the city, but extended to the Ainsty, which was originally a hundred or wapentake of the West Riding, bounded by the river Ouse, the Wharfe, and the Nidd, and a line from the town of Thorp-Arche on the Wharfe to Cattal Bridge on the Nidd. The city of York appears to have held claim to this extensive jurisdiction in the reign of Edward I., as having been granted by a charter of King John; but their claim was disputed: it was finally confirmed by a charter of Henry VI. By the late act the Ainsty is separated from the jurisdiction of York, and annexed partly to the West Riding and partly to the Pocklington union.

It is impossible to form any conjecture as to the extent of the population of York during the early periods of its existence. It appears from Domesday-Book that in the reign of Edward I., if the city be divided into seven wards, one of these belonged to the archbishop, and one was destroyed for the castles. In the remaining five wards there were 1418 houses, and in the ward of the archbishop 200. Supposing, with Drake, that in the ward devoted for the castles that many houses as to make the whole number 2000, and allowing five inhabitants to each house, the population at the Conquest would amount to 10,000. Drake supposes further that the suburbs contained an equal number of persons, and thus the whole number of York in the 12th century being at 20,000, as corrected, he thinks that when the survey was made between the sixteenth and twenty-first years of the Conqueror's reign, a great devastation of the houses had taken place, and the population must have been proportionately diminished. If the number of inhabitants be again corrected to 10,000, and the number of church buildings reckoned, he supposes that the population had greatly increased again in the time of Stephen, when thirty-nine of the churches are said to have been destroyed by fire; and it must have been considerable in the reign of Richard II., when the tenth of the church buildings were destroyed. In the sixteenth century, supposing the number of the population to be 11,000 inhabitants were destroyed in 1390 by pestilence. In the various vicissitudes experienced by the city, the number of its inhabitants must have varied. In the time of Edward II., when the metropolis of the northern counties, the population amounted to no more than 16,000. Since that time it has been nearly doubled; the census in 1841 giving 28,883, of which number there were 13,423 males and 15,450 females. But in this census one parish and part of another without the walls, forming in reality a part of York, though belonging to the North Riding, are excluded. Including these, the return is 29,500.

York from its foundation has never ceased to have the appurtenances of a free borough, and as the city was the residence of the archbishops of York and the seat of the diocese, it have been a centre of learning and one place of residence, and since the love and admiration of the clergy has been extended to all the inhabitants of the city, they have been of the most cosmopolitan character. The city, as it was, and as it is now, is a very fine city, and a very fine place for a day's pleasure; and in the area of the Roman walls there is a walk of about 500 yards, which till recently must have been a complete morass. The extent of the walls is about two miles and a half; a very considerable portion of them is accessible to the public, which, having lately been put into a state of complete repair, from the completion of the new entrance and gates, which were, perhaps, the most important of the gates, and the most imposing wall. There are four principal gates, or bars, as they are usually called, and five postern gates. Two new entrances through the ramparts have been recently formed; one of them exclusively for the railway, the other for road traffic, which has not to have been erected within the walls; another entrance, which had been closed since the time of Henry VII., has been re-opened. The castle has long since been converted into the county prison and the courts of justice
for the county; but some portions of the old work, besides
the noble keep, are still remaining. The felons' galley is an
entire new building, consisting of four radiating double
wells, with eight airing courts, the governor's house being
in the centre. The keep, known by the name of Clifford's
Tower, the Cliffsords having been the antient wardens of
the castle, is generally supposed to have been built by the
Conqueror, but the architecture indicates a somewhat later
period.

That York was not a strong military station only, but
also a place of trade even in the times of the Romans,
is by no means improbable; its situation being as conve-
venient for commerce as for war. Aelcin, in the eighth
century, says that York was a common market of land and
sea; and says that it was then visited by vessels from the most
distant lands. In the tenth century several merchant
vessels on their voyage to London from York were cap-
tured, and it is supposed that it was the route for the export
trade for the whole kingdom was fixed at Calais, the merchants of York had a considerable share in this
trade; some of them being mayors of the staple of
Calais, and one of them is named as having been the tree-
sureman of the staple of Calais; and they had a long
manufacture of woolen goods. In the days of Henry II.
and Henry III., the weavers of York paid a considerable 'firm' for their
privileges; and the manufacture was flourishing in the reign
of Henry VIII.

But this branch of trade has long
ceased to flourish here, York having not now the
breadth of any extensive manufacture. It has however been long
celebrated for the making of leathern gloves, shoes, combs,
and other articles of horn. During a long period these were
the staple trade of the city, but they are so no longer; yet York, in proportion to its population,
is the seat of respectable and steadily increasing trade, di-
vided into various branches. It has one extensive flax-nail;
many bands are employed in the manufacture of linens;
and York is said to have been as a high character in due
time, the guild of merchants at York all the privileges
which they and their houses had before enjoyed. By a statute
of Edward III. it is directed that the staple of wool, leather,
woolens, and lead, should be at York and nine other places
named in the act. In the reign of the fourth successor, the
first for the export trade for the whole kingdom was fixed at
Calais, the merchants of York had a considerable share in this
trade; some of them being mayors of the staple of
Calais, and one of them is named as having been the tree-
sureman of the staple of Calais; and they had a long
manufacture of woolen goods. In the days of Henry II.
and Henry III., the weavers of York paid a considerable 'firm' for their
privileges; and the manufacture was flourishing in the reign
of Henry VIII.

But this branch of trade has long
ceased to flourish here, York having not now the
breadth of any extensive manufacture. It has however been long
celebrated for the making of leathern gloves, shoes, combs,
and other articles of horn. During a long period these were
the staple trade of the city, but they are so no longer; yet York, in proportion to its population,
is the seat of respectable and steadily increasing trade, di-
vided into various branches. It has one extensive flax-nail;
many bands are employed in the manufacture of linens;
and York is said to have been as a high character in due
time, the guild of merchants at York all the privileges
which they and their houses had before enjoyed. By a statute
of Edward III. it is directed that the staple of wool, leather,
woolens, and lead, should be at York and nine other places
named in the act. In the reign of the fourth successor, the
first for the export trade for the whole kingdom was fixed at
Calais, the merchants of York had a considerable share in this
trade; some of them being mayors of the staple of
Calais, and one of them is named as having been the tree-
sureman of the staple of Calais; and they had a long
manufacture of woolen goods. In the days of Henry II.
and Henry III., the weavers of York paid a considerable 'firm' for their
privileges; and the manufacture was flourishing in the reign
of Henry VIII.

YORKSHIRE, a maritime county in the northern part of England, and by far the largest of the English counties, is bounded on the north-east and east by the North Sea; on the south by the estuary of the Humber, and the counties of Lincoln, Nottingham, and Derby; on the south-west by a small part of Cheshire; on the west by Lancashire; on the north-west by Westmoreland; and on the north by Durham and the mouth of the river Tees. Its form is irregular, the greatest length of the county in a straight line is from the projecting point called Spurn Head, on the south-east, to the juncture of the counties of Westmoreland and Durham, on the north-west, a distance of about 124 miles. In the opposite direction, from the estuary of the Humber and Cheshire to the same point on the western boundary, which approaches within 10 miles of the west coast of Lancashire, the length of the county is about 100 miles; and its extent from the extreme south point, at the juncture of the counties of Derby and Nottingham, to Tod Point, at the mouth of the Tees, in a direction nearly due north, is about 92 miles. The county is comprehended between 53° 18' and 54° 40' N. lat., and between about 9° E. and 2° 36' W. long., from the meridian of Greenwich.

Yorkshire is divided into three Ridings, which are called, from their respective positions, the North, West, and East Ridings, and from the year 1295, by virtue of the Nebraska War, and the doctrine of the Popes, are divided into nine wapentakes, called Hundreds, and in the Population Returns and many other statistical documents these divisions are treated as distinct counties. The parishes of Crake, near Easingwold, though geographically forming part of the North Riding of Yorkshire, are therefore omitted in the following statement of the areas and population of the great divisions of Yorkshire. The population is here given from the Census of 1831, for the sake of comparison with other counties, those in the preceding section having been corrected as necessary; and in the Return of that year. The population in 1841 is given in a subsequent page, under the head of Statistics. The areas given in the Population Returns for 1831, from which the following figures are taken, somewhat exceed the aggregate of the areas given in the returns of 1841, as an attempt is made in the Returns to reconcile the apparent discrepancy:

Whole county 3,830 3,735,040 1,371,550

The gross area of the county is more than one-tenth that of England and Wales, and more than one-ninth that of Great Britain. Its population, however, exceeds that of any other English county, excepting Lincolnshire and Devonshire, while that of the North Riding is nearly equal to Norfolk, the fourth of the English counties in superficial extent. The area of the whole county of York is greater than that of any of the counties of London, Devonshire, and Hertfordshire, and it considerably exceeds the aggregate areas of the ten smallest English counties. According to the returns of 1831 the population of Yorkshire averaged nearly 22,000 persons to a square mile, which is rather below the average for the whole of England, and above that of the three counties which approach nearest to it in superficial extent. York, the capital city, is in about 53° 56' N. lat. and 1° 3' W. long. It is not much more than 170 miles by the white sea from London to the coast line, but about 190 miles by the main road from London to Edinburgh, and about 202 miles from the latter city.

York is situated on the banks of the river Ouse, which flows from the White Cliffs, and 12 miles above the city, the river is crossed by a bridge 526 yards long. The town of York stands on the south bank of the river, and that of Beverley on the north, which are both distant about 11 miles. The south bank of the river, the most northern portion of the coast-line of the county. This estuary terminates at Tod Point, about 54° 37' N. lat., and from that point to Whitby, a distance of about 24 miles.

Borders and Coast-line.—The coast of Yorkshire is generally high, and consists in many places of precipitous cliffs. The south-eastern side of the estuary of the river Ouse, north of the town of York, is the most northern portion of the coast-line of the county. This estuary terminates at Tod Point, about 54° 37' N. lat., and from that point to Whitby, a distance of about 24 miles.
measured in a straight line, the coast, which consists of cliffs abounding in fossils, runs in a very irregular line towards the south-east, without presenting any place of importance. One of the cliffs, about seven miles north-west of Whitby, is marked by Greenough as having once taken fire, and is now separated by a gap of two years. At Whitby, which is situated at the mouth of the river Esk, is a harbour which, though exposed to gales from the east, has been so much improved as to be capable of carrying on a considerable trade. A few miles south-east of Whitby, the coast turns rather more to the west, and is separated slightly by the dangerous bay called Robin Hood’s Bay, towards the southern extremity of which, not far from the coast, is a hill popularly called Robin Hood’s Butts. From this point the coast proceeds south-south-east to Scarborough, where an elevated position which projects abruptly towards the east, with an arm towards the south, forms a semicircular harbour, which is much used for shelter from the easterly gales that are common along the Yorkshire coast, and which forms the only port of any consequence between Whitby and the mouth of the Humber.

The distance between Scarborough and Whitby, in a straight line, is about 17 miles; and from Scarborough south, the coast-line again inclines more to the west, to the western point which is variously called Filey Point, Filey Head, and Filey Bridge, near the boundary-line between the North and East Ridings. Immediately south of Filey Point is Filey Bay, from which the coast runs in a nearly straight line by Speeton Cliff to Flamborough, which, forming a promontory, is next to the north, a series of chalk cliffs, of brilliant whiteness, about six miles long, and rising in many places to an elevation of 300 feet. At the base of these cliffs are some extensive caverns, and near the extremity of the promontory, on a site about 250 feet above the level of the sea, is a light-tower erected by the Trinity House corporation in 1806, and which has a revolving light of sufficient intensity to be seen from a distance of 30 miles at sea. In thirty-six years preceding the erection of this important lighthouse, there were 124 wrecks in this portion of the coast, though its establishment has almost put an end to such casualties. The eligibility of the spot for the establishment of a beacon would seem to have been observed long before a regular lighthouse was placed there, as the name of the village of Flamborough is supposed to be derived from the practice of placing a light or flame at that point in early times. From Flamborough Head, which is 18 or 19 miles in a direct line from Scarborough, and about 50 miles from the mouth of the Esk, measured in this manner, the coast turns westward, and then sweeping round to the south, forms the capacious bay called Bridlington Bay, upon the coast of which the sea has made such encroachments as to gradually sweep away the villages of Auburn, Harbourn, and Newby, while the addition of the whole coast has been defended by two batteries, at Bridlington Quay, which is about a mile south-east of the town of Bridlington. From Bridlington Quay to the sharp-pointed promontory which terminates the Head, the coast is defended by two batteries, and for 17 miles, by shortliffe bent. Beyond these is a small promontory formed by two bays, from the north-east, and which is a good shelter for vessels. In this northern boundary of the estuary of the Humber, the coast-line is broken by many inlets or points of land. Greenough marks the sites of two churches, those of Owthorpe and Kilnsey, in the south-eastern part of this portion of coast, the ruins of which are partially washed away by the sea. At Spurn Head, which is about 40 miles south by east from Flamborough Head, and which consists of a long low promontory turning towards the south-west, part of the estuary of the Humber, and termed the Humberside, made considerable encroachments upon it; but of late it has receded so much as to leave extensive tracts of marsh land. One of these, a few miles westward of the Spurn Head, began to appear as an island about the commencement of the reign of Charles I., and, increasing from year to year, it was at length embanked and converted into pasture. In the Population Returns of 1841 this tract of land, though now only separated by a ditch from the mainland, retains the name of Sunk Island, is stated to contain 550 acres and 2240 inhabitants. The northern part of the coast-line of Yorkshire is rocky, and from the mouth of the Tees to Scarborough the cliffs, which are always washed by the sea at high-water, and in some parts at low-water also, are generally from 70 to 130 feet high, and often rise abruptly and overhang the beach. In many places they are still higher, and at Stoupe Bro, or as it is more commonly called. Snow Bridge, south of Robin Hood’s Bay, and about seven miles south of Whitby, they rise to the height of 600 feet above the sea. In the vicinity of the elevated promontory of Flamborough Head there are also cliffs of the height of 100 feet, and in places separated by upland of the same height. From Spurn Head westward to the confluence of the Ouse and the Trent, a distance in a right line of about 35 miles, the southern boundary of the county is formed by the Humber; and although the line is very irregular, in general it is in the vicinity of the coast, and is occasionally marked by some unimportant stream, such as the general direction to the north-west, and passes a little south of Shepley Head, and across the elevated and mountainous district called the Peak of Derbyshire. [Dunmore]

The next point of the boundary is the mouth of the Esk, where it joins the river Tees, at a point about 50 miles west by north of the Tod Point, the northern extremity of the Yorkshire county. The Tees, flowing by Barnard Castle, Yarm, and Stockton, forms the northern boundary of the county by this river, a mile west of the Esk. The boundary of the North Riding is coincident with that of the county on the north-east, north, and part of the west; but leaving the latter at a point about 22 miles south of the junction of Westmoreland and Cumberland, runs 18 miles to Barrow-in-Furness, thence forming an irregular course east by south to the river Duddon, or Y°, until 3 miles below Milnthorpe, and then follows the course of that stream to Ripon, where it turns off across the north shore of the Tees, and rejoins the river above Boroughbridge and Aldborough, and follows its course as far as York. Then and for some miles higher up, the river is called the Ouse. It then turns east, and afterwards north-east, to the Bever, which it joins at Stamford Bridge, and thence the course of that river by New Malton, to one of its sources near the coast, reaches the sea at a point near Filey Head, which separates the county from the East Riding.

The boundary of the North Riding is coincident with that of the county on the north-east, north, and part of the west; but leaving the latter at a point about 22 miles south of the junction of Westmoreland and Cumberland, runs 18 miles to Barrow-in-Furness, thence forming an irregular course east by south to the river Duddon, or Y°, until 3 miles below Milnthorpe, and then follows the course of that stream to Ripon, where it turns off across the north shore of the Tees, and rejoins the river above Boroughbridge and Aldborough, and follows its course as far as York. Description of the Surface, &c.—The most striking feature in the formation of the surface of this county is the great valley drained by the Ouse and its tributaries, which stretches from near the Tees, in the northern part of the county, to the estuary of the Humber in the south, having a general direction from north to south-east, and forming the northern slope of the most extensive valley in England, that of the Ouse and Trent. The high land on the eastern boundary of this valley, extending from the source of the rivers through their lower division of the Wolds, and terminated, a bold coast-line, from which, in the northern part of the county, the surface rises, in some parts very suddenly, to a great elevation. In the description of this valley and its boundaries, in the "Physical and Political Geography of England," I have already alluded to the Wolds, and observed that south of the estuary of the Tees we find the commencement of the high lands, which, in some places stretch inwards to a distance of from 20 to 30 miles from the coast. The Wolds, which have an area of about 744, in the trigonometrical station of Beverley Moor, and a little farther south, in the Guisborough Hills. These high lands run down to the sea-coast at Huntcliff, and also by the Easington Hills, about midway between the Tees and the Wolds, which in a straight line to the coast, a distance of about 30 miles from the coast. The whole tract of the Wolds, from the coast to Driffield and Beverley, 15 miles west, and 15 miles north from south, is a wild and mountainous district, intersected by numerous picturesque and fertile valleys, and forming an escarpment towards the west, which rises round towards the south and east from 100 to 300 feet, at Driffield, and Beverley. It forms a line tolerably parallel, in its general direction, with that of the coast, North of Driffield, where the rugged extremity of the highlands turns eastward, it overtops the coast, with rising to the height in many places of upwards of 1000 feet, the general aspect of this district, which is sometimes called the North York Moors, is bleak and dreary, especially as it is almost entirely destitute of trees. On the south side of the valley, the land descends to the sea, and the dreary wastes present themselves, with no boundary to the horizon; but towards the northern and western escarpments of the moorlands there are some very beautiful prospects. The steepest side of the elevations is generally on the north and east, lying eastward of the coast, which is the eastern boundary of the Ouse valley, and embracing the Eastern Moors and the valley of the Derwent.

The valley of the Derwent, which descends from near the sea-coast, in the neighbourhood of Scarborough, and, delaying towards the south-west, at Finningham, which is the southernmost promontory of the eastern coast, and the eastern boundary of the valley of the Ouse, separates the Eastern Moorlands from the Yorkshire Wolds, which form the continuation of the high lands on the east side of the valley of the Ouse. One portion of this range extends from the neighbourhood of Tantallon, on the Derwent, near the mouth of the Humber, west of Hull, following a course very nearly parallel with the coast-line, and terminating to the south in an escarpment which seems to push the river a little out of its direct course, and which commands most beautiful and diversified views, embracing the great estuary of the Humber and the opposite shores of Lincolnshire, as well as the low lands of Yorkshire on each side of the range. Upon this portion of the Wolds are the elevated points of Walton Beacon, about twelve miles east by north from York, with an elevation of 800 feet, and Humsey Beacon, farther south, with an elevation of 531 feet. The highest point of the Wolds extends in an easterly direction to Flamborough Head, forming the southern side of the Derwent valley. The ascent of the Wolds, excepting on their eastern side, is generally steep, but they seldom rise to an elevation exceeding 400 feet, and then it is usually in the form of deep winding valleys. Although their southern extremity presents the finest prospects, there are many points on the range from which beautiful views may be obtained of the vale of York, the low grounds, behind a short range of Spurn Head, and the valley of the Derwent, beyond which the Eastern Moorlands rise in the background. Flamborough Head, which forms the most prominent point on the coast, is not the most elevated of the cliffs which muzzle the eastern extremity of the Wolds; the highest point is at Bempton Cliff, a few miles farther north, which rises to an elevation of 436 feet. Speeton Cliff, about midway between Flamborough Head and Filey Point, is the extreme northern limit of the great chalk formation which separates the district, consisting of the south-west coast, at Sidmouth in Devonshire. On the eastern side the chalk Wolds terminate in a line which, commencing near Bridlington, and running south-west for a short distance, curves round to the south, and, passing through a series of hills, which are known as the Heale and Hull. The portion of the county which lies between this range on the north and west, the ocean on the east, and the Humber on the south and west, forms the low district of Holderness, the highest point of which, close to the town of Hornsea, is the largest lake of the county, called Hornsea Mere, about a mile and three-quarters long, and three-quarters of a mile broad at the widest part. The western side of Holderness is distinguished by the marshy prospects of the Pans, which, extending nearly 10 miles from north to south, with an average breadth of about four miles. As noticed in a previous column, considerable portions of land have been reclaimed from the Humber, and a large district of reclaimed land has been obtained by cutting through the district by Beverley, and falls into the Humber at the place to which it has given its name, has been drained under an act of parliament obtained in 1762. This level, which is called the Holderness Drainage, extends about 11 miles from north to south, and comprises 1,211 acres, and before it was drained the land was of very little value, because much of it was under water for one half of the year. Thirty years later an act was passed for the Beverley and Barnston Drainage, which includes a similar district on the opposite side of the Hull, extending from the sea-coast at Barnston, a little south of Bridlington, very nearly to the town of Hull, a distance of about 24 miles. This drainage has two outlet, flowing east into the sea, and the remainder of the level, amounting to about 10,000 acres, into the river Hull. The Keyingham Drainage, which lies further south, in the promontory which terminates at Spurn Head, was formed under an act passed in 1762, but extended, so as to embrace about 5500 acres, by another Act obtained in 1802. In addition to the great extent of fertile land added to the county by these drains, the high prices of agricultural produce in this country has been the cause of an increased extension of cultivation on the Wolds, which, until about the close of the eighteenth century, were little better than a large rabbit-warren. The valley of the Derwent, and its tributary the Harford, or Hertford, has been so much increased in the Act of 1800, of the Hertford and Derwent Drainage, comprising more than 10,500 acres, of which 4500 belong to the East, and the remainder to the West.
Riding. Under the provisions of the same Act, Spalding Moor and Walling Fen, which lie to the west of the south-eastern extremity of the Wolds, between them and the Ouse and Derwent, were drained and flooded.

On the western side of the great valley of the Ouse lies the Western Moorlands of Yorkshire, the general elevation of which is much greater than that of the Eastern Moorlands. These form part of the irregular tract of high land called the Pennine Chain, which, with the Cumbrian Mountains, the Derbyshire and Staffordshire hills, forms the most mountainous district in England. The highest point of the Pennine Chain is at Cross Fell, a few miles north-west of the village of Cross Fell, where the Westmoreland and Durham, and approaches within three or four miles of Cumberland; and from a little south of this point, which has an elevation of 2901 feet, is a ridge nearly coincident with the county boundary, with a steep escarpment towards the eastern side of the valley of the Eden, the abrupt elevation of which forms a contrast to the long and gradually sloping arms sent off on the east side into Yorkshire and Durham. South of this point the Cumbrian Mountains join the western side of the great Pennine range, the high lands coarsely in its further progress towards the south, sometimes spread out into extensive moors, sometimes present rounded mountain-tops, and in other places consist of a confused heap of rocky mountains, interspersed with numerous narrow valleys, which are strewn with fragments of the meteoric matter that has fallen. This portion of the range, which occupies the north-western extremity of the West Riding, forms the western portion of the wild district of Cranen, and comprises, among other heights, Wharfedale, near the summit of Wharfedale, Netherdale, near the junction of the counties of York, Westmoreland, and Lancaster, with an elevation which, according to Greenough, gives as 2384 feet, according to the Ordnance Survey, or 2461 feet, according to W. Allen, Esq.; Ingleborough, which is farther south, is 2691 feet, according to the Ordnance Survey, or, according to Mr. Allen, as quoted by Greenough (who gives the elevation as that of Ingleborough Hill and Simon Fell), 2412 feet; Pen-y-neyant, or Penninag, rather more to the east, about 2270 feet, having a summit near that of the Great Whernside, on the boundary of the counties of Yorkshire and Westmoreland, and still more to the east, 2363 feet; Bow Fell, near Sedbergh, a few miles north of the first-mentioned Whernside, which would appear by Greenough’s statement, apparently from the Ordnance Survey, to be 2911 feet high; an elevation considerably greater than that of any other mountain in this part of the country; but we find no other authority for the statement, and the Ordnance Survey of that part is not yet published; and Cam Fell, near the two Whernsides, which, according to the same authority, is 2245 feet high; this little known peak, little to the south-east of Skipton, is Rommel’s or Rumble’s Moor, with an elevation of 1318 feet. The valleys of this district, the most extensive of which are Nidderdale or North Riding, and the valley of the Wharfe, in Airedale, are so well wooded, cultivated, and studded with villages, as to present a beautiful appearance from the adjacent heights; and the picturesque character of the district, the roads of which afford some of the finest scenery in the country, is heightened by numerous small lakes, one of the principal of which is Malham Water, or Malham Tarn, 6 or 7 miles east by north of the town of Settle, which is about a mile in diameter, and is situated upon the summit of Malham Moor. Another small lake belonging to this mountain region is called the Simmer or Summer Lake, near Askrigg, in Wensleydale, which, together with the valley of the Swale and several others of minor extent, breaks up that part of the Western Moorlands which belongs to the North Riding. Though the general direction of the great range of mountains which occupies the western side of the county, and which is sometimes styled the back-bone of England, is from north to south, it does not consist of a single break, but of a number of ranges which, though perfectly irregular in their disposition, mostly form small angles with the main direction of the mountain-range, thereby forming numerous long and narrow valleys, with a great number of small lakes from north to south. This lofty district forms a kind of natural boundary between York and Lancashire, and presents great difficulties in the way of communication, especially by canals or roads. These difficulties however have not deterred engineers from the construction of both, though they meet with the execution of some extraordinary and costly works. The general character of the surface is the being flat towards the river Ouse, and having an undulating surface towards the Western Moorlands on its opposite boundary.
Geology.—In this great county, which stretches from the eastern to nearly the western coast of England, a great proportion of the stratified rocks of the British series may be advantageously observed; the exhibitions of igneous and miscellaneous, in almost every interesting character; the rich and varied deposits, are extensive and remarkably so; the series of ancient organic life is extremely large.

The leading physical features of the county are very obviously dependent on its geological structure, and the modifications to which they are subject by the action of the sea and modern atmospheric agencies, are various and instructive.

If through the city of York a line be drawn to the north-north-west and south-south-east, it will pass along the banks of the Humber. In the north these banks are lifted very gradually above one hundred feet above the sea. Were the general level of the land altered by a depression quite within the limits of well known instances, this vale would be a sea-channel, bordered by the cliffs of an island on the east, and more slowly rising lands on the west. The district on the west rises to assume a mountainous character along nearly all the western border of Yorkshire; the eastern region is somewhat mountainous in its northern portion, and in the southern rises into a curved range of hills, 'the Wolds,' between the flat district of Holderness and the vale of Pickering.

The elevated western district is based on Palaeozoic rocks; the central vale and the larger part of the eastern region are chiefly composed of chalk and clay. In Holderness, and in other limited tracts are tertiary and diurnal deposits which may be referred to the Cainozoic period.

In the condensed descriptions which follow, the deposits are arranged in the order of their relative position in the earth.

Cainozoic Deposits.

Alluvial.

Silt Lands.—The great rivers of Yorkshire which converge in the Humber, flow in all their lower parts through vast breadths of fine sediments, left by the rivers and the inundations of the sea, and a great portion of this silt is still below the level of the spring-tides, and only 

dasured from floods by banks.

In the valley of the Aire, at Ferrybridge, hazel branches are petrified, and nuts with the kernels changed to calcareous stone, were found in considerable numbers. (Phil. Mag., 1829.)

Post or Turf Moors, at no higher level than the silt and just noted, occupy extensive areas (Thorne Waste and Hatfield Chase), and in some situations deposits of silt, as much as 20 or 30 feet thick. Trees in considerable abundance lie in these deposits, and have been stated to show traces of the axe and marks of fire.

De la Prune, in Phil. Trans.

In such peat, on Thorne Waste, skeletons of the fallow deer, and in one remarkable case the bones were found to have lost their carbynous phosphates and carbonates, and by the action of sulphuric acid to have been subsequently converted to leather by the action of tannin on the remaining gelatine. (Reports of the British Association, 1831.)

Shelly Marks.—Under the peaty tracts of Holderness, which are of remarkably small extent, lie marls often filled with lizardine shells; and amongst them really the remains of the Irish elk (Ceritnx giganteus) have been found.

Raised Beaches. The shelly gravels and sands of some tracts near Bridlington, in Holderness, may possibly deserve this name, but more certainly applicable to some shelly sand-beds on the coast between Flamborough and Agglestone, from which several marine shells of existing species have been extracted.

Diluvial Deposits. Accumulations of local gravel are common in the valleys of most parts of Yorkshire, but over great breadth of the district of Holderness, in some of the coquet and chalk hills, and in many of the valleys in these formations—over great part of the area of the central vale of York—In the elevated country between the Swale and the Tees, and in very few situations in the valley of the Calder, occur deposits of gravel of various sizes and qualities, which have been drifted from great distances, even from beyond the limits of the county, especially from the north or north-west. Of these gravel some are of a size to arrest attention, and of such a peculiar nature as to be easily referred to the original situation from which they were drifted. Such in particular at the "termine banks" of porphyritic granite, which lie near the surface in many situations in the northern and eastern parts of Yorkshire, on areas which converge to the north-west, and finally terminate in the porphyritic granite fans of Shap in Westmorland. From that area they were swept across ridges of hills, and great breadths and valleys, as far as Flamborough Head and Scarborough; but whether by force of water, when the land was at a lower level, or was rising out of the sea, or by icebergs floating on water, or by glaciers moving across the land, or by a combination of these, is still a problem for discussion. A great proportion of small drifted stones lies in a great body of clay which is not stratified, and incloses stones of all sizes, without any arrangement of size, gravity, or mineral quality. Bones of the elephant, hippopotamus, horse, ox, etc., occur in these gravelly and argillaceous deposits, but not frequently, except in valleys where the materials may have been displaced and subjected to fluviatile action.

(Yale of York; Middle... On the Wolds, etc.)

Ostlerous Deposits.—At Hessle cliff, flinty gravel, covered by a diurnal clay, contains elephant's and other remains: at Belbeds, near Market Weighton, marl which has some drifted sand below and other gravel above, and fossils agin, fish, eggs, and some bones of other animals, with 13 species of land and fresh-water shells of existing species. Few of the numerous caverns in Yorkshire, which occur in the great limestone districts of the North Riding, have been explored for bones. The Cave of Kirkdale is the only subject of some curious remarks by Dr. Brodie's description (Reliquia Diluvianae), which enumerates more than twenty vertebrated animals among the relics.

Tertiary.

On the sea-coast, immediately north of Bridgeford Quay, green and ferruginous sands enter into the composition of the drift, and, under favorable conditions, have been explored with success, and have yielded a considerable number of shells of tertiary date, perhaps of the age of the crag of Suffolk, in which some of the species certainly occur.

Mesozoic Strata.

Cretaceous System.

Chalk (500 feet thick).—It constitutes the Wold Hills. This is usually a harder rock than that of the South of England, and the nodular flints which it contains are scattered through a great part of its thickness. The lower parts assume in places a greyer and softer aspect. Fossils abound in the upper part, and the chalk is marked by echinodermata, but mollusca and conchifera are less plentiful than in the South of England. The lowest band of the chalk is red, as in Lincolnshire. The chalk is unconformable to all the strata below, resting on each of them in which it rests in different parts of the Wold edge, as far as the lower beds of the lias.

Skepton Clay (150 feet thick).—This blue argilaceous deposit lies under the chalk, but does not graduate into it. It appears on the coast at Skepton, and inland at Knaph and other points. The organic remains are numerous, different from those in the chalk, and also different from those in the strata below. They appear to have analogous to the golt of the South of England, and also to the Kimberidge clay; the former analogues perhaps predominating, which the shells occur abundantly in the North of France, which are supposed to be nearly equivalent to the lower greensand.

Orichic System.

Kimmeridge Clay.—This occurs along the south side of the vale of Pickering, and under the extreme south of Wolds near Cave. It is not clearly seen in contact with the Skepton clay above, into which it perhaps passes. It contains Ostrea dentata.

Upper Cretaceous. 500 feet thick.—This section, as seen on the hills above Wiss Bank, and near Brotton, contains a few fossils.

Cornish Cretaceus 60 feet thick.—This rock forms the uppermost stratum of the series of strata...
Oolitic grains are of various sizes, some beds being coarse pisolithic. A few bands of chert nodules occur in it, and crystallizations of calc-spar and quartz, and deposits of calcere, lie in the cavities left by the decomposition of organic remains. It is not generally durable in buildings. In this rock is situated Kirkdale Cave. Several rivers sink into it, and reappear after long subterranean passages. These cavities are extremely numerous; the coral beds being local, but characteristic.

Lower Calcareous Grit (80 feet thick).—It forms the edges of the tabular hills above mentioned, and occasionally broad and very poor heath surfaces. Though calcere and ferruginous, it has little carbonate of lime in its composition, and some of the shells which it contains are silicified. Locally it is a good building-stone. The fossils are very numerous, and almost exactly like those of the same rocks in Oxfordshire. Ammonites vertebralis is common.

Oxford Clay, or grey earth of Scarborough Castle Hill (150 feet thick).—It appears in the steep slope of the escarpments of the tabular hills, under the 'Nab Ends,' and on the breast of the sea-cliffs south of Scarborough. The fossils which it contains are not in such abundance as those of the Oxford clay of the South of England.

Kelloways Rock, or Hackness Rock (90 feet thick).—It lies at the base of the tabular hills, and is the rock at the foot of the sea-cliffs south of Scarborough. It is more ferruginous than the calcereous grit; is in places somewhat oolitic; and everywhere rich in fossils, such as Ammonites calloviensis, A. subulavis, Gryphaea dilatata, and other shells characteristic of the same rock in Yorkshire, where it is a quarter of a mile thick. The Hackness rock has proved a fair building-stone in the museums at York and Scarborough.

Cornbrash (10 feet thick).—This impure calcereous rock is developed from the sandy Kelloways stone by a thin band of clay containing crustaceas. It is very rich in fossils, and is nearly continuous from Scarborough to the vicinity of Mallaun.

Below the cornbrash, the oolitic series of Yorkshire is very thin, unlike that of the South of England. In this is little sandstone, in this little limestone; the clays of the South are shales in the North; and with the shales and sandstones are fossil plants, coal-beds, and ironstone layers, very much like those of the older coal-fields. To these strata it is not desirable to apply always the same names as those which belong to (perhaps) contemporaneous beds in the South, but we shall indicate the probable analogies.

Upper Sandstone, Shale, and Coal (nearly the equivalent of the Hinton sands and Forest marble of Somersetshire) (200 feet thick).—This series of sandstones (conglomeratic, or fine-grained, or laminated), shales, coal, and ironstone courses, may be studied about Scarborough, and in the Vale of Pickering, in the direction of the northward. The coal is thin and of small value.

Grey Limestone (equivalent of part of the oolite of Lincolnshire), 30 feet thick.—It occurs at the White Nab, south of Scarborough, at Cloughton, and on the other points north of Scarborough and west of Whitby, always in an impure, rarely at all oolitic state. But as we turn south along the foot of the Hambleton Hills, it becomes oolitic, and, as the upper and lower sandstones diminish, it thickens and acquires more of the usual oolitic aspect. It is generally a very ferruginous rock, and the organic remains are not numerous. They agree partly with those of the cornbrash, and partly with those of a lower zone, to be mentioned below.

Lower Sandstone, Shale, and Coal, 500 feet thick. Thesed, of this great mass of arenaceous and angulaceous deposits is thick enough to be worked on the moors west of Whitby and north of Helmsley, and on the sea-coast at Hainton Wyle. Over it is a bed of sandstone, in which showe of equisites stand erect, and below is a bed of coal. This series of rocks ascends to the highest parts of the Cleveland Hills, 1800 to near 1900 feet above the sea.

Ferruginous Beds (inferior oolite and sand of Somersetshire), 60 feet thick.—These appear in the Peak Hill at Robin Hood's Bay, at Kettleburn north of Whitby, and in various places round the base of the Cleveland and Hambleton hills, as Osmotherley and Crake Castle. In the Peak Hill the slightly calcereous and iron beds are very fossiliferous, and the species of fossils generally resemble those of Dundry Hill near Bristol. The transition from these beds to the limestone below is very easy and gradual, the base of the one and the top of the other being softened by intervening pale micaceous sands.

Upper Lias Shale, called also alum shale, from having the principal seat of the manufacture near Whitby, let house and workshops at Guisborough, as well as at the works near Whitby, and in the Cleveland hills it gradually loses the thickness in going to the South of England, till near Rievaulx and at Lyme Regis it can hardly be said to exist at all. In these strata lie most of the Sa urian remains and many of the ammonites, belemnites, and other shells for which the Whitby coast is famous. It yields coniferous wood, and changed to jet.

Marlstone.—A series of sandy, ferruginous, and siliceous calcereous beds, which divides the lias shales into parts, and is very rich in fossils, receives this name. At Robin Hood’s Bay, Staithes, and the head of Bliak, it is very conspicuous. Thickness 150 feet. These are the strata which contain opiliius rather frequently freed Stitches.

Lower Lias Shale (500 feet thick).—It forms the base of the loamy cliffs to the west of Staithes, and supports the high moorlands of the carbonaceous sandstones and shales. It continues its thickness, and in its lower part, there are bands of gyptrites, especially where its course approaches the Humber. Hardly any true lias limestone rock occurs in Yorkshire farther north than about the town and Market Weighton. The ammonites and other kinds of shells and the fossil sea-clam of the Lias of Yorkshire, Somersetshire lias, and it contains coniferous wood, are sometimes changed to jet.

New Red Formation.

Red Marls with Gypsum.—These marly clays, with thick occurrences of gypsum (Pooleys, Weighton, Holme), form a band on the eastern side of the vale of York, at the south foot of the oolitic and chalky hills, but, being much eroded by gravel drifted against these hills, are less known for thickness and properties than any other of the fossil strata. They may be several hundred feet thick. It contains no fossils.

Red Sandstone.—This is found on the western side of the vale of York, in an irregularly undulating tract of country, especially about Ripon and Boroughbridge. It has with it a considerable mass of white or yellow sandstone, but near Boroughbridge. Its thickness is unknown; it contains no fossils.

Palesclonic Strata.

Magnesian Limestone Formation.

Brotherton Limestone (45 feet thick).—This is a pure grey limestone, much laminated with clay, and nearly void of magnesia; a few shells occur in the lower beds: they may be several hundred feet thick. It contains no fossils.

Red Clay and Gypsum (50 feet thick).—This is very thin in the vicinity of Fairburn and Brotherton, and has been cut through on the York and North Midland Railway. It separates the nearly pure limestone of the red sandstone from the subjacent red sandstone, and is a continuous bed of rather wet land. No organic remains occur.

Magnesian Limestone (150 or 200 feet thick).—The composition of this important rock is usually a mixture of carbonate of magnesia and carbonate of lime. It has the appearance of the red sandstone, but the structure is atomic. The magnesian limestone is generally of thick, and the grains are often crystalline. Colour usually yellowish, and the quality excellent for the mason, but of uncertain durability. Hildesleyton and Roche Abbey stone are the best in request. Tadcaster yields abundance of lime, and is of good. Spar veins and cavities are uncommon. Small veins of carbonate and sulphate of copper, oxide of iron, sulphate of barytes, and sulphate of stromatococcus occur in the rock. In the vicinity of Garforth the lower beds are often laminaed, north of Whitby, and in the districts of Durham, and yields products and other fossils. Attn. myrtii, nautii, spiral shells, and few corals occur in the limestone near Ferrybridge. The springs which...
Coal from the magnesian limestone often contain carbonate of lime, but seldom much magnesia. The course of the magnesian limestone is in a range of low tabular hills from Mardham, by Harewood to Roche Abbey. These hills are finely escarp to the west and slope gently to the east. The soil is not in general good, especially for grass, but it is applicable to various cultivation.

Observations on the Red Sandstone. or Pontefract Rock. — In places this is 100 feet thick, and consists of brown, purplish, and yellowish sands and clays, with stems and other parts of plants. Near Pontefract it is usually a mass of yellowish sandstone, of the greatest excellence for the use of the metal-founder, and the construction of moulds. This is a property which accompanies it along a great part of its course, which is a narrow belt, on the west side of the magnesian terrace. Between this and the strata beneath it exist several searches for a complete history of the coal formation.

Carboniferous System.

Coal Formation. — From beneath the southern part of the nearly straight edge of the magnesian deposits are the sandstones, shales, ironstones, and coal of the West Riding of Yorkshire, and fill an enormous area in the valleys of the Aire, Calder, Went, Dearm, Dove, and Dun. Leeds, Bradford, Halifax, Huddersfield, Penistone, and other towns, are built to the whole of these strata, while Aberford, Kippax, Pontefract, Elmstall, Conisborough, and Laughton le Morthen are near its straighter eastern boundary. The whole of this large area is penetrated in the shales and sandstones, and only the whole of the district is about 4000 feet thick; and of the coal which lies in this series there are about 20 workable beds, yielding about 40 feet of coal, generally of good quality. Ironstones of excellent quality accompany the lower parts of this bed, and the circumstances of the country permit the full attainment of all these advantages.

In this great coal-field the most useful classifications are made on the nature and accompaniments of the beds of coal. The most complete general view yet made is that given by Dr. Whitaker, in his valuable Geological Map of the County, founded on the succession of grit rocks and shales containing coal and ironstone.

The following is the classification of Dr. Smith, proposed in 1821:

1. Pontefract rock.
   a. Shales and coal beds.
2. Ackworth rock.
   a. Shales and coal.
   b. Chevet rock.
4. Red rock.
   a. Shales and coal.
   b. Bragdore rock.
5. Shales and coal (the shell ironstone).
7. Shales and coal.
8. Flagstone and other rock.
   a. Shales and coal.

The Pontefract rock is here ranked by Dr. Smith among the coal-measures.

Below is the millstone-grit series. The Ackworth rock yields soft freestones, and grindstone occurs at Ackworth, Kirby, Mexborough, and Denaby. The Chevet rock is of limited range and little value. The Red rock, often a coarse gritstone, occurs at Woolley Edge, Newmiller Dam, and Bragdore rock yields freestone and grindstone. The Wortley rock is thin in bed. The flagstone is evenly laminated, micaceous, and yields fine paving and roofing flags.

Beds of coal are worked in the west of Yorkshire as this is 18 inches, yields Huddersfield, and near Barnsley, from 9 or 10 feet (Barnsley), but the average is from 3 to 6 feet. The finest coal of Bradford (called the 'better bed'), and some of the finest Silurian coal, may be viewed near the town of Newcastoe and Durham P. C. No. 1794.
makes in the vicinity of Clithero and Settle, round Pendle Hill, Ingleborough, and Penyghent, mighty ranges of rock four or fifty feet thick, and nearly perpendicular. Farther north and west, near Kirkby Stephen and Brough, it begins to show shaly sandstones, and beds of coal and as we advance into Northumberland these interpretations grow more and more important, the limestones grow thinner and less pure, and the whole group resembles closely the Yoredale rocks as they are seen in Yorkshire. The rock exposed in the mountains above Grosmont Hill in Nidderdale, in Warkworth, in Riddlesdale, about Settle, Clapham, Ingleton, and Kirby Lonsdale. In these cases they are full of caverns of great size and beauty, sometimes giving subterranean passage to the rivers, and forming cavernous breadths here and there. Lead and copper are found in veins in this limestone, but not very frequently. Calamine occurs in it, in the district of Bowland Forest, and oxides of zinc on Malham Moors. The organic remains of the mountain limestone in Yorkshire are extremely numerous and interesting.

Old Red Sandstone.

This rock hardy occurs in Yorkshire except as a conglomerate, locally accumulated in the valley of the Rother, near Rotherham, and not in connection with the mountain limestone which rests on the slaty Silurian rocks, and in its lowest beds contains pebbles of those rocks and lumps of quartz.

Silurian System.

This class of strata appears to be unconfonnable to the limestone series above. It is found in two separate districts: one near Sedbergh, west of the summit of drainage, and naturally associated with Wensomerdale, rising into a characteristic group of hills called Howgill Fells; the other, running almost east and west on the north side of the mountains of Graygarth, Ingleborough, and Penyghent. In both localities slates cleavage disguises the original stratification of the Silurian sediments; the slates are developed at the crest of the moor, near Sedbergh, and about Horton in Riddlesdale, and at Ingleton a greener rock is left in tolerable slate. It is a most singular geological scene which is presented in the vicinity of Ingleton and Horton, for there slate rocks of extremely various qualities, with vertical cleavage and inclined beds, are covered for many miles by a horizontal cap of mountain limestone 500 feet thick. Orthoceras and other fossils occur in the dark thin flags of Horton in Riddlesdale.

Disturbances of Strata.

Such is the series of Yorkshire strata, much thicker, more complete, and more varied than belongs to any other county of the empire. It will be found that three cases of general vertical movement of the strata are of great importance have been noted: the first is between the Silurian and the mountain limestone; the next between the coal and the magnesian series; the last between the oolitic series and the chalk. The prevailing dip of the strata is eastward; indeed, except in the western parts of Craven and in the line of great faults, this general dip is very little modified. In the district of Craven several anticlinal axes of limited extent, mostly ranging north-east, make very slight elevations about Greenhow Hill, Skipton, Lothersdale, and in Bowland Forest. These are often connected with the production of metallic veins. A slight broad anticlinal axis affects the oolitic strata beneath the chalk.

Some of the dislocations, which occasion great vertical movement of the strata, are very striking. The Great Craven Fault, which ranges nearly east and west from Wharfdale to near Kirby Lonsdale, and is in part of this course double, causes a downfall to the south of from 1000 feet to more than 1000 yards, and is accompanied by a distinct and characteristic change of physical geography. North of this line the country rises to the height of 2000 feet, and south of it sinks to a few hundreds of feet. Where this fault turns to the north from near Kirby Lonsdale, and runs in the name of the fault, its effect are everywhere extraordinary, and the western border of Yorkshire derives its peculiar bold escarpment from Wharnside to Mickle Fell from the operation of this fault.

These general curious faults visible in the oolitic and lime strata of the coast near Whitby, and the coal-field is full of them. The magnesian limestone is dislocated near Robin Hood's Well and in a few other places. These and many other fractures of the earth's crust are wholly or principally unconnected with great masses of igneous rock, and devoid of such rocks along the line of failure. Under Ingleborough however a curious red felspathic dyke is seen to coincide with the Craven fault, and a very large and valuable gravel deposit is accompanied by a dislocation of strata, traverses the northern parts of this county, and the southern part of Durham. Some of these beds are near Middleton in Teesdale to near the High Peak, south of Whitby. Along the line of this great 'whinstone' are great quantities of water-falls, and causes the great waterfalls of the Tees and Forest of Bowland. Here are westward 200 feet in others 24 feet thick. It is a sort of 'interposed bed,' which was formed from lava poured out on the sea-bed with some violence and rending of the strata. It is in a few places absolute, and varies in crystallization. The lake have been altered by its heat to white crystalline mass, the sandstones hardened, and the shales locally changed so as to yield in one spot garnets. No particular failures appear to mark its course, and its relation to the local faults of Teesdale and Alston Moor is obscure. Lead-vines traverse it in mines about Hilton and Dunto and yield ore, a circumstance in which it appears to differ from the limestones of Durham, which is also interposed in the limestone of Teesdale.

The authorities employed in the compilation of this sheet of the geology of Yorkshire are chiefly the publications of Professor Phillips (Geology of Yorkshire, vols. i. and ii. Geol. Transactions, 1827; Phil. Magazine and Rev. pass. Professor Smith (Geol. of the county of York, and Dr. Smith (Geological Map of the County). In the Geology of England and Wales, by Conybeare and Phillips, are many useful notices.

Climate.—The great extent of the county of York and the variety of surface over which it is distributed, give rise to considerable differences of climate in various districts. In his 'Geographical View of the Agriculture of the North Riding of Yorkshire,' published in the year 1800, observes that the climate is very much colder than at any other place. From its situation, cold and bleak winds from the north-east and north-west, and especially from the north, traverse the district from the cold August to the cold December. The country is less influenced by heavy rains, impinging in a more severe manner upon these hills, according to the course of the wind. An elevation of about 700 or 800 feet, and a country much rarerified by the warmth of the day, either ascend above the summits, or remain upon them at an elevation in proportion to their rarefaction. As the autumn approaches, the temperature falls; the ground begins to be covered with frost, and the winter season sets in. In the month of November, the winter begins to be more severe, and the spring and autumn months are nearly of equal extent.

In the winter and spring the wind is generally from the north, n.-w. and w., with frequent squalls from the east and east-south-east; but in the summer and autumn the winds are from the north, n.-w., and w., with squalls from the south-west and south-south-west. The climate is generally healthy and salubrious.
The Ouse, which is sometimes called, to distinguish it from other rivers of the same name, the Northwold, is formed mainly by the union of the Ure or Yorc and the Swale, and, according to Langdale and some other writers, takes the name of Ouse at the junction of those streams, about three miles below Boroughbridge, although on some maps it is continued for several miles lower down, to the junction of the Linton. It is stated under Trent and Humber that the total length of this stream from the source of the Swale may be estimated at 130 to 135 miles, and it appears to be about the same if we add the name of the Ure or Yorc as the main stream, which several writers do.

The Ure rises in the high mountains at the western extremity of the North Riding, near to the border of Westmorland, and in close proximity to the south extremity of the Lake of the Eden. It flows first towards the south-west, and then eastward, near Hawes and Askrigg, along Yoredale and Wensleydale to Middleton, receiving in its course several small tributaries on each side, especially on the south side, where it receives one stream from the Simmer lake and another from Bishopdale. A little below Askrigg the Ure falls over a succession of limestone rocks, forming what is called the Aysgarth Force. Below Middleton it is joined on the south by the Cover, a stream of the head of the lower valley of Coverdale; and shortly afterwards it turns more to the south and flows past Masham, a few miles below which place it reaches the boundary-line between the North and West Ridings, and receives on the west side the small stream of the River Bim, which has its origin in the parochial low hills that gradually subside into the level plain of the county. It then pursues a very irregular course by Tankfield to Ripon, where it receives from the right-hand side, one of the principal streams of this county, the former of which rises near Segsworth Fell and flows by Fountain's Abbey. Though a small stream, the Skell is of great utility to the inhabitants of Ripon by supplying them with excellent water. At Ripon the Ure quits the boundary, and enters the eastern district, first running to the south, then to the east, forming the boundary between the north and the much more important river Nidd on the Ouse river. The Ouse runs about 4500 miles north from the York, and from that city near Cawood its course runs southward, into a little inclining to the west, and forms for the most part the boundary between the Ainsty and the East Riding. Near Nun-Appleton, a little above Cawood, it receives the Wharfe, which forms the southern limit of the Ainsty, and in the remaining part of its course the Ouse constitutes the boundary between the East and West Ridings. Inclining now to the south-east, it pursues a very irregular course by Cawood and Selby, and after receiving successively the Derwent from the north, and the Aire with its tributaries from the south-west, it pursues a very tortuous course near Howden, and by the newly-formed post of Goole, where it is joined by the Don. To the north of York, the Ouse rises and descends through various valleys and passes into the ocean. [Trent and Humber.] The Humber is navigable as far as Hull for ships of the largest burthen, and from seven to eight miles upstream from the mouth of the Don. Vessels of 140 to 150 tons burthen can ascend the Humber as far as York, while barges of 30 tons may ascend the upper part of the river. The Ure is navigable for barges up to Ripon, and the Ure and Don can be ascended by vessels of 30 tons. More than half a century since a lock 21 feet wide and 70 feet long was erected on the Ouse at Naburn, four miles below York, previous to the formation of which the tide ascended above that city, and, according to some accounts, flowed to the height of four feet at the Ouse Bridge.
York, a distance of 80 miles from the sea. But according to a map of the environs of York, published by W. Palmer in 1725, and referred to in the 'Geography of Great Britain,' the spring-tide was only two feet at York, six feet at the mouth of the Wharfe, and ten feet at that of the Derwent. The same writer refers to Drake's 'Eboracum,' to show that the greatest rise at York, before the lock was made, was two feet or two feet and a half, and observes that these facts serve to show the nature of the York plain, and that a very small permanent change in the water-levels of the sea and land would turn the valley of the Ouse up as far as York, and the corresponding valley of the Trent as far as Newark, into sandy estuaries. The Ouse and its principal northern tributaries have been the subjects of several acts for the improvement of the navigation; and Priestley, who gives a full account of these, observes that notwithstanding the limited trade of that portion of the Ouse above the city of York, it 'has such an immense traffic in the lower part, by reason of the numerous rivers and canals immediately communicating with the manufacturing districts of Yorkshire and Lancashire, in addition to the coal-mines, stone-quarries, and various iron-works situated in the West Riding, as will undoubtedly rank it the second river of the kingdom in importance and use by its union with the Humber. Manufactures of the merchandise is exported to and imported from all parts of the world.'

The Swale is formed principally by two streams, which, rising respectively near two hills called the Lady's Hill, and Flaw Hill, are its sources from the Ure, and the latter of which has an elevation of 2239 feet, flow in an easterly direction along the opposite sides of the high ground called the Water Crags, which has an elevation of 1220 feet, until, after the said mentioned and principal branch having turned to the south, after flowing through the valley called Swale Dale, they unite at Muker. From Muker the river has an irregular course towards the east to Richmond, before reaching which place it receives several other tributaries, principally from the northernmost part of its basin. The most important being the stream which flows along Arkingley and Aysgarth Dale, and the little river Marske. Below Richmond its course inclines somewhat to the south, and it receives, together with several minor streams, the river Ouse on the left bank. On reaching Bowes near Northallerton, it inclines suddenly to the south-south-east, and runs parallel to a ridge of hills which separates it from the valley of the Wiske; and in this part of its course it receives on the western side a considerable stream, which, rising near Cogdon Haugh, at a very considerable distance from the upper course of the Swale, flows past Bedale, and conveys the drainage from several other streams into the Swale, and also affords facilities for navigation, which, being cascaded, many falls, is so changed by improvements; but though an act was obtained for the purpose, the intended navigation was never completed. Langdale styles this stream Bedale-beck, but it is sometimes called the Bedale river. A few miles farther south, in the latitude of Thirsk, the Swale is joined by the Wiske, a stream which rises near Osmotherley, on the west escarpment of the Eastern Moors, and after flowing for some distance northward towards the Tees, turns westward past Great Smeaton, near which place it is crossed with some small lakes, and then turns southward beneath Dunkery Wiske, and near Northallerton, until, having passed the southern termination of the ridge which separates it from the Swale, it inclines westward, and joins that river. From this juncture, in the course of the Swale Dale, it continues its south-south-east direction to its junction with the Ure, receiving in its course two considerable streams which descend from the Hambleton Hills, on the escarpment of the Eastern Moors, the northern and most important of which is the river Ure. It also receives, running up the peculiar rock 286 feet high, which forms the centre of a romantic amphitheatre of limestone rocks called Malham Cove, of which there is a view in Dr. Whittaker's History of Yorkshire, a little above Cowood, and which may be considered the termination of the high land in this direction, the ground to the east of that place forming part of the great level of the Vale of York. The course of the Swale, wherever it forms the boundary-line, is wholly within the West Riding of Yorkshire, though very tortuous.

The source of the Aire, Air, or Aire, is in Malham Tarn or Water, five or six miles east by north of the town of Settle, in the district of Craven, among the Western Moors, and is about a mile south from this lake which gives it its name; but for about a mile south from this lake the river runs through the most remarkable part of the country, a peculiar rock 286 feet high, which forms the centre of a romantic amphitheatre of limestone rocks called Malham Cove, of which there is a view in Dr. Whittaker's History of Yorkshire, a little above Cowood, and which may be considered the termination of the high land in this direction, the ground to the east of that place forming part of the great level of the Vale of York. The course of the Swale, wherever it forms the boundary-line, is wholly within the West Riding of Yorkshire, though very tortuous.
whether the stream which issues from Malham Cove is actually that which enters the earth at Malham Tarn; but according to the statements of others in that county, in seasons of heavy rains, the Tarn overflows itself, the waters spread themselves over the surface of the rocks; and at length reaching Malham Cove, are precipitated over the centre of the precipice in a vast cataract. This phenomenon, which also rises one of the most extraordinary among the contracted dimensions of the subterranean channel, the opening of which, at the base of the Cove, is at such times evidently sufficient for the escape of the swollen and turbid stream. The course of the Aire, and of those streams which rise in the Calder, as it winds its way through the Calder valley in a direct line, is generally towards the south for a few miles, until, near Gargrave, it is crossed by the Leeds and Liverpool Canal, which passes over it by a large aqueduct at an elevation of 111 feet above the sea at low water, and which from that point follows the valley of the Aire. The Calder, and the levels of which, hereafter noticed, will give some idea of the descent of the valley. From Gargrave the general course of the river is south-east, passing to the west of Skipton, in which town there is a fall of 495 feet, of Keighley, and north of Bradford, along the picturesque valley of Airedale, to Leeds, in passing its course the ruins of Kirkstall Abbey. At Leeds the canal terminates, the river itself being made navigable below that town. The Calder receives the river Wharfe there, where it receives the Calder from the west, and from which point it pursues a very irregular course, the main direction of which is nearly due east, but inclining a little to the south, by Knottingley, Ferrybridge, and Kellington, and passing the town of Wakefield, which is west of the northernmost side of the Calder. From the south, and from this junction it runs east by north for five or six miles (direct distance) to its junction with the Ouse at Askeldy Island, near Armin, or Airmyn, a little to the east of Pontefract and near Wakefield, with the Aire, with its important tributary the Calder, for the purposes of navigation, forms an important feature in the history of this class of improvements, these rivers having been made navigable under the powers of an act passed in 1825, and which vessels of 100 tons burthen, prior to the date of any enactment for a canal navigation. As before intimated, the Aire is not navigable above Leeds; but under the powers of the act referred to, the navigation was formed, from that town to the junction with the Calder, the distance of 11 miles, in which there is a fall of 495 feet, effected by six locks, and also from the junction of the two rivers to Weeland, a farther distance of 18 miles, with a fall of 314 feet, by four locks, making a total navigable length of about 30 miles, with several short constrictions, and extending to quarries and collieries in the vicinity. An unsuccessful attempt had been made to obtain an act for his navigation as early as 1823, and when it was revived, the act passed in 1825, and under which the navigation has been formed, for the proprietors of the Aire and Calder Navigation Company, were given powers to have formed a canal from Ferrybridge, through Knottingley, which runs in a direction nearly parallel with the river, but more rectified, and lying south of it, by Egborough and Heck, to the junction of the Ouse at Goole; the eastern portion of this canal, from the Don to the Ouse, being merely parallel to that branch of the Don, or Dun, which is commonly called the Dutch river. The total length of this cut is about 18 miles, and it falls, to low-water mark at Goole, 293 feet. Goole was the most important town on this branch of the river, containing only a few houses; but in consequence of the construction of the canal, and of the place having received, in 1828, the privileges of a port, it has risen so rapidly in importance as to contain, in 1841, 479 houses, and a population of 3,008 souls, as stated in Mr. Remie, but executed by Mr. George Leather. By the various improvements which have been effected from time to time by the Aire and Calder Navigation Company, the navigable has been rendered available for vessels of 100 tons burthen, which are aided by steam-tugs, as far as Leeds on the Aire, and Wakefield on the Calder. For the Calder, the principal tributary, the Aire rises on the high ridge called the ‘Backbone of England,’ just beyond the county boundary, in the adjacent county of Lancaster. Its principal source is in a marsh in Olivers Dean, a little to the south-east of Burnley, from which rises also the feeder of the West Calder, a stream which, flowing westward, joins the Ribble. The waters of its several sources are collected together in the deep and romantic valley of Todmorden, and flow with a very winding course through a deep and often exceedingly romantic vale, before reaching the town of Sowerby, about two miles south of Halifax, north of the hill called Bank Top, by Elland, Dewsbury, Horbury, and Wakefield, from which place it inclines a little towards the north to its junction with the Aire at Castleford. The course from near Todmorden to Hollinshead and the Rochdale Canal runs in the same narrow valley as the Calder; and as this valley has also been selected for the turnpike-road and the Manchester and Leeds Railway, there are many parts along several lines of communication jostle and intersect each other in a most remarkable manner, the valley being frequently so narrow as scarcely to leave room for them all. The river has consequently been diverted from its natural course in several places by such lines of communication, the streams which descend from the high lands on each side of these the principal are a stream which joins it on the south side, near Sowerby Bridge, at the foot of the Bank Top mountain; the Hebble, a rapid stream which descends from the mountains near Hebden Bridge, near Halifax, and joins the Calder at the termination of the Rochdale Canal; the Colne, which rises near the boundary of Derbyshire, and flows by Holmfirth and Huddersfield in the northern and north-eastern direction, which has several sources in the country between Barnby and Wakefield, and flows north by west into the Calder. The portion of this river which was made navigable by the Aire and Calder Navigation Company, and which now forms the main branch of the canal, extends a distance of about 27 miles, with a fall of 212 feet, effected by twenty-eight locks, forms the connecting link between the Rochdale Canal and the Aire and Calder Navigation. The line was surveyed by Smedley, and under the act passed in 1798, but improved and extended under subsequent Acts, one of which, passed in 1825, empowered the proprietors to branch a canal from Halifax. The difficulties attending the formation of this navigation, besides those of any other works in the valley of the Calder, by the number of mills established upon the streams, the rights of which has been necessary to regard. These difficulties, in the case of the Halifax branch, led to the supply of the canal with water by means of a drift 1170 yards long, from the basin of the canal at Saltershebbie to a pit beyond the uppermost lock, whence it is raised to the summit level by a steam-engine. In this branch, though only 1 mile in length, there is a rise of 1004 feet. Several short private canals and railways communicate with the Calder valley, the charter of the company of the Don or Dun, the only remaining tributary of the Aire which requires special notice, rises near Saltersbrook, upon the high ground called Snealiden or Snailaden Pike, near the border of Cheshire, and a few miles west by north of Penistone. It pursues an easy direction, and has been extended to the latter place, and then turns south-east towards Sheffield, receiving on its way the little Don Dun, which rises near the same point, but flows in a straighter direction along Mickapebble-dale; the Ewen brook, the many small streams passing farther south, descending from the high lands on the border of Derbyshire, and skirting the northern escarpment of Bradford Moor, and the Loxley river, which descends from the southern escarpment of the Bradfield, meeting two or three short tributaries, which, from the Riveling, descends from Lord’s Seat, near the county boundary. For the whole of this distance, and also for some miles below Sheffield, the Don rises again, feeder from the north or north-eastern
hemmed in by a ridge nearly parallel to its course. At Sheffield it is joined by the Shaf or Sheaf, which rises in the Derbyshire mountains, and runs north-north-east, and receives another small stream from the south-west. From Sheffield the Don runs north-east by Rotherham and Doncaster to Thorne, where it turns north, and runs to the Aire just below Skanith. The principal tributary of the Don up its course is the River Rother, which rises in Derbyshire [D'Anvilles, vol. viii., p. 418], enters Yorkshire a few miles south of Rotherham, and joins the Don at that town; the Dearn, or Darwen, the largest stream in the region which rises in the hill called Down Moor, to the north of Penistone, and flows first north-east and then south-east, collecting the waters of several tributary streams, by Barnsley and Darfield, below which place it receives from the west the little river Dove, to its junction with the Don near Conisbrough; a stream of considerable length which descends from Hemsworth, Kirkby, and Clayton in the Clay, and flows westward to the Don at Barnby, and the Went, which originates in the last slope of the high lands on the west of the Ouse valley, and flows by Wentbridge and Kirk-Smeaton to the Don about midway between Thorne and its junction with the Aire, receiving some minor streams in its way.

The navigation of the Don or Don reaches commences at Thorne, south of Rotherham, at which point the river rises, and is continued by the Sheffield section of the general system of navigation, although part of it is derived from the general system of navigation, though forming part of the same extended line of communication; but in many parts below that point a navigation is effected by artificial cuts to avoid bends and determines the bed of the river. The first act for the navigation was passed in 1726, and there have since been several others, of which that of 1828 empowered the company of proprietors to make very extensive improvements by new cuts and other works. The portion of navigation from Thorne to Doncaster, which by the old course is 21 miles long, is reduced to 18 miles, with a fall of 674 feet by eleven locks. From Doncaster to Fishlake Ferry, near Thorne, the navigation is continued in like way, sometimes in the old course of the river and sometimes by the new, and is continued by further improvements from 12 to about 101 miles. From Fishlake Ferry to New Bridge, near Snaith, is a distance of 54 miles, and from this point the antient and natural course of the Don was, as before stated, nearly due north to the Aire; but the navigation, instead of proceeding along it, turns east-south-east to the Ouse by the nearly straight cut called the Dutch river, the length of which from New Bridge to Goole is 52 miles; and in consequence of this the old course in the old channel has been allowed to silt up. The channel of the Dutch river formerly consisted of two parallel ditches, cut during the reign of Charles I. by Sir Cornelius Vermuyden, for the purpose of draining the lowlands in the vicinity of Hatfield Chase, and its success is shown in the immense reduction of the lands so benefited. In 1688, during a great flood, the sluices at Goole were carried away, and the ditches, which consequently obtained entrance to the drains, destroyed the intermediate division, leaving nothing but the outboard works, and converting the channel into a very wide canal, which at high water during spring-tides is navigable for brigs of 300 tons burden. The bridges over this channel are made moveable, to allow the passage of masted vessels. The total length of the improved Don navigation is about 310 miles, with a total rise from low-water mark in the Dutch river of 924 feet, effected by six locks. Priestsley says that when the tide flows 15 feet at Goole it will only flow 7 feet at Fishlake, and 34 feet at Barnby Don Ford. Besides the cuts made by the Dutch, the navigation is joined by several private cuts from the Masborough Iron-works and the Greensborough coal and iron works; and Priestley observes that it is of the utmost importance for exporting the produce of the extensive coal and iron works which abound at Barnby Don Ford. Principal among the manufactured iron goods and cutlery produced in Sheffield and its neighbourhood. The trade of Rotherham, the limestone and plaster at Spratbrook and other places on the west side of Rotherham, and of the agricultural produce of the neighbourhood of Doncaster, also contribute considerable branches of traffic; while the imports embrace every article required for the supply of an extensive and populous manufacturing district.
mbly; and the river Costa, or Pickerick-beck, descends from Stakehole Moor, along Newton-dale, and by the town of Pickerick. From the junction of the Rye, which gives rise to the waipenteke of Ryedale, the Derwent flows by New Malton through a beautifully diversified district, past the town of Selby, and turns south-east, forming the eastern boundary, when the course of the River Hull, which rises near the county boundary at Grindleton, it turns south-west above Osburne, and continues in this direction along the border of the county for a few miles, past Clitheroe, until the boundary turns northward, while the Ribble pursues its former direction through Lancashire. The Hodder also, a feeder of the Ribble, rises in this county, near Bolland Knott, to the west of Settle, flows south-west to the boundary of Lancashire near Blesdale Moor, and turns north-west forming the county boundary as far as its junction. For a further notice of these rivers see Lancashire, vol. xii., p. 290. The Tees joins the county boundary at its north-western extremity, at the junction of Yorkshire, Westmorland, and Durham, in the Lune Forest, and it continues to form the boundary between Yorkshire and Durham for the whole of its course from that point to the sea. This river itself is not sufficent here to notice its principal tributaries on the Yorkshire side, which are as follows: the Lune, which rises near the border of Westmorland, and flows north-east through Lune Forest, collecting rivulets from the hills on each side, to the Tees a little below Middleton; the Bander, which flows in the same direction, and enters the Tees about midway between the junction of the Lune and Barnard Castle, passing in its course those hills in Stanhope Forest which, in consequence of the height of Robin Hood's Bay, near the name of Robin Hood's Butts; a similar stream which enters the Tees at Barnard Castle, and is called the Deepdale river; the Greta river or beck, sometimes called the Barney, the longest branch of which enters the Tees near Barnard Castle, and pursuing the same general course towards the north-east by Great Bridge to the Tees, a considerable length between Bowland and Brignall being nearly due west and east, and, after part of its course towards the north, small streams which rise near Brignall, and, flowing nearly parallel with the Tees towards the east, passes by Birsting, Hutton, Stanwick, and Barton, to the Tees at Croft; and the Leven, which collects the waters of numerous rivulets from the northern part of the Eastern Moors, rises near the Tame from the vale of Cleveland, and, flowing westward by Stokesley to Rudby, thence turns north by a winding course to the Tees below Yarm. Still further eastward, small streams rise on the south side of Cleveland, and, flowing directly to the sea, one of the principal being that which passes by Guisborough and enters the sea at Saltburn.

The other streams which rise in this county, but soon cross the boundary into the adjacent counties, are of but little importance; the chief one is the river Derwent, which rises to the east of Rotherham, flows westward into Lincolnshire, and there joins the Idle; the Tame, a tributary of the Mersey, which leaves Yorkshire at its junction with the Cheshire and Lancashire; the Wenning, at the border of Westmorland and Lancashire, which rises north-west of Settle, and flows westward into Lancashire; the Greta, being a second rivulet of that name, which rises at two points near Wharnside, and, flowing westward into Lancashire, unite, and turn westward across the county boundary to the Lune, a short distance north of the Wenning; the Dee, which rises north-east of Wharnside, flows west by north along Dent-dale to Sedbergh, where it enters the western county, and, after forming the county boundary for a short distance, enters the Lune in Westmorland; and the River, the second river in the county of that name, which rises on the north-west boundary, near the sources of the Eden, flows first north-west across the Yorkshire, and then turns southward by the Calf and Castler Crags and the hill called Seter to Sedbergh, where it receives a stream which flows west through Gardale, and below which place it joins the Dee.

**Grammar.**—The North Riding of Yorkshire is almost entirely destitute of either artificial canals or navigable rivers, and the canals of the East Riding are few and unimportant; but the West Riding is peculiarly rich in the species of communication, while the exceedingly difficult state of the country through which the principal canals have been conducted has rendered necessary the construction of engineering works of astonishing boldness and magnitude in order to effect navigable communication.
of the section given by Priestley of the inland navigation between the ports of Liverpool, Goole, and Hull, by the river Mersey, the Duke of Bridgewater's and Rochdale Canals, the Calder and Hebble Navigation, and the rivers Ouse and Humber, a distance of 1584 miles by that route. Commencing along the tideway of the Mersey, the level is suddenly raised by locks at Runcorn to an elevation of about 90 feet above the level of the Manchester. The next material rise takes place beyond Manchester, on the Rochdale Canal, which, in a distance of 17 or 18 miles, rises to the summit level near Stansfield, at an elevation of 600 feet above low-water line on the Mersey, at Liverpool, according to the section, or, as it was termed by Walls, the Inland Navigation of Great Britain, which with Priestley's work was published as a book of reference, 6100 feet above the sea at low-water. From this point, which is about 90 miles by the navigation from Liverpool, and a very short distance west of the western boundary of Yorkshire, the level of the canal falls very suddenly to Todmorden, and after entering Yorkshire continues to descend, until, at the junction with the Calder and Hebble Navigation, about 73 miles from Liverpool, the elevation is only about 270 feet. From this point the descent, though far less rapid, continues considerable until arriving at the junction of the Calder and Hebble and Aire and Calder Navigations at Wakefield, while the total fall in the remaining distance of about 62 miles, is only about 300 feet. Other lines of communication from the Irish Sea to the German Ocean are formed by the more circuitous route of the Leeds and Liverpool Canal, together with the Aire and Calder Navigation, and the more direct routes of the Aire and Huddersfield canals, which communicate with the Calder and Hebble Navigation through Sir John Ramsden's canal. For convenience of reference the principal canals of Yorkshire may be noticed in alphabetical order.

The Calder and Hebble Navigation has been sufficiently noticed under the rivers from which it takes its name. It forms a connection between the Ouse and Humber on the south-east, the Leeds and Liverpool Canal on the north-west, the Calder and Hebble Navigation on the west, and the various artificial rivers of the south, and runs through several private canals and railways to mines and quarries, especially in the vicinity of Leeds and Wakefield.

The Barnsley Canal was formed under an act of the year 1799, additional capital being raised by the company for paying off their debentures, and opened by a second act in 1806. It commences in the Calder, a little below Wakefield Bridge and the junction of the Calder and Hebble Navigation, and proceeds southward for about 10 miles, and from first 21 miles of it is effected by 15 locks. It then turns westward, and, after crossing the river Dearne by a stone aqueduct and forming a junction with the Dearne and Dove Canal, passes Barnsley and extends to Barnby Basin, in the township of Cawthorne. It communicates with the Silsden collieries. The latter part of its course has a rise of 40 feet by five locks, but of its total length of 151 miles 11 miles form one level. This canal was opened in 1799, and has been both highly profitable to the proprietors and useful to the neighbourhood, introducing Silsden stone coal to the London market, and aiding the cultivation of the moor-land in the vicinity of Barnby Basin.

Beverley is a short canal or creek connecting Beverley with the river Hull, which presents a fit state for navigation under acts passed in 1726 and 1744.

The Bradford Canal, formed under an act of 1771, and completed in 1774, is a cut of about three miles from the Leeds and Liverpool Canal southward to the town of Bradford. The cut is 864 feet by ten locks. It is very useful for exporting paving-stone, coal, and iron from the neighbouring parts, and has been the main cause of the establishment or extension of several iron-works, some of which communicate with Bradford by private railways. Wool is also an article which this canal is instances in the importance of the soil manufactures of Bradford and its vicinity.

The Calder and Hebble Navigation, a considerable portion of which consists of artificial works, is noticed under Sir John Ramsden's Canal, the Rochdale Canal, and by its branch, with the town of Halifax on the west. It was projected solely for the purpose of affording facilities to the manufacturing district west of Wakefield, but it has become of more importance in the navigation by the Rochdale and Huddersfield Canals, and the artificial rivers and canals by the artificial rivers and trees by the materials of Manchester and Rochdale were brought by land-carriage across the central ridge of mountains to this navigation at Sowerby Bridge, but the opening of the canals occasioned a vast accession of inland traffic and brought very large profits to the proprietors of navigation.

The Chesterfield Canal, which belongs chiefly to Nottinghamshire and Derbyshire [Norton Manning, vii., p. 399; Deazavaxis, vol. ii.,] and runs from the southern extremity of Yorkshire between Shire Oak and the village of Wales, near which there is a tunnel of 56 yards upon the summit level of the canal.

The Dearne and Dove Canal, constructed between the years 1739 and 1760, commences at Dewsbury, in a spot which forms part of the Dun or Don navigation, and proceeds north-west to the aqueduct for conducting the Barnsley Canal across the river Dearne near Barnsley, a distance of 25 miles, with a rise of 12 feet, by eight locks. It has a branch of two miles to Worksop, and is connected by a railway with extensive collieries on Stainbro' Hall; and there is also a branch canal 15 miles, belonging to Earl Fitzwilliam, to the latter works. The chief objects of this undertaking are the communication of this district about its water-extremity, and the exportation of the manufactures of Barnsley through the port of Hull.

The Derwent River Navigation is sufficiently noted in the account of a stream under the name of the Derwent.

The Driffield Navigation commences in the river at Aike Beck Mouth, about 44 miles north of Beverley, and about 1420 miles north of the junction of the Leven and the Aire. For a distance of 20 miles northward the rivers are navigable, chiefly as artificial rivers, and are continued by the short distance up Frodingham Beck, the chief head of the Hull, which has a short private cut-off to Foston Hall, but a little north of the junction of Frodingham Beck with the Hull the canal leaves the former, and proceeds to Kirkbridge, a distance of 127 miles, and then passes into the Humber, and finally into the south. The navigable canal, formed under an act of 1767, is used for the importation of coal from the West Riding, timber and merchandise from Hull, and the exportation of wool and other produce.

The Dun or Don River Navigation is described under the river Don; so likewise is the Foss Navigation under the river Foss.

The Hedon Haven Navigation, from the Humberside is an artificial river of Holderness, is of very little importance; it was the subject of an act passed in 1856. It is a natural creek or stream improved for the purpose of navigation.

The Huddersfield Canal, which was formed under an act of 1787, and acts passed in 1800, and 1806, is one of the most important works in the kingdom, considering its limited extent ever executed. The projectors perceived that it was possible to form a canal in a tolerably direct course between that made by Sir John Ramsden from the Aire and Hebble Navigation to Huddersfield and the Aire-under-Line Canal, then approaching completion, was to supply the most direct line of communication between the eastern and western seas, and they determined opening the present line, which was surveyed by Mr. John Browne; but the almost unprecedented difficulties of the works compelled the proprietors to increase the capital before the central portion was completed; this part of the canal was opened in 1798. The canal as far as Huddersfield is fitted for water traffic, and is capable of admitting boats of twenty-four tons burthen, commences the south of the town of Huddersfield and crosses the river Colne. A branch canal is in consequence of the importance of the manufactures of Bradford and its vicinity.
are hauled through this tunnel by manual labor in about an hour and twenty minutes. Emerging from the tunnel at Diggles, the canal pursues the same direction by Siddaleworth, through it a second time, and by the same route for several times, and after running parallel with the boundary of Lancashire for some miles, it turns westward near Duckinchfield, and passes for a very short distance through the valley of the Calder, its junction with the Ashton Canal. Its length from Huddersfield to the summit-level is 74 miles, the level itself 4 miles, and the descending slope, which has a fall of 3334 feet, by thirty-three locks, 84 miles, making a total length of 194 miles. The summit tunnel, which winds through the tunnel, is 5 feet wide and 17 feet high, the depth of water being 8 feet, and the height above the water 9 feet; and there are on the western slope two other tunnels of 204 and 136 yards respectively.

The navigation across the island by this route is 22 miles short, and by the use of its utility to the manufacturing district through which it passes is very great, both in the importation of raw materials and the exportation of manufactured goods.

The Huddersfield and Leeds Canal, which extends about three miles eastward from the river Hull to Leven, for the conveyance of lime, manure, corn, and other produce, was formed by a private individual, under the powers of Acts passed in 1801 and 1805. It is sometimes called the Leven Canal.

The Knottingley and Goole Canal, forming part of the Aire and Calder Navigation, has been described in connection with the river Aire.

The Leeds and Liverpool Canal, which is partly described in the Notice, vol. xii., p. 290, commences at the north-western termination of the Aire and Calder Navigation at Leeds Bridge, proceeds a short distance along the river Aire, and then enters an artificial tunnel, which pursues the course of the river on the south side of that river, following all its windings to Shipley, where it receives the Bradford Canal, having a rise in this portion of its course of 158 feet 7 inches. From Shipley it proceeds westward to New Mill, where it enters an aqueduct, which is crossed by the road from which the name of Gargrave is derived. This aqueduct, 800 feet long, is near the summit-level of the canal; the descent is about 35 feet to the river, and is concluded by a lock. Beyond Gargrave the canal turns south-west, crosses the Aire again by a large aqueduct, and runs southward across the Craven Moors, attaining at the summit-level at Greenfield, near Todmorden, the summit-level of the canal, and 200 feet above the level of the Aire at Leeds. Beyond Gargrave the canal runs north-west, crosses the Aire again by a large aqueduct, and runs southward across the Craven Moors, reaching at the summit-level at Greenfield, near Todmorden, and 200 feet above the level of the Aire at Leeds, and about 500 feet above the level of the sea at low-water. On the summit-level it receives a branch from the Hainstone-quarries at Rainhill Rock; and this canal continues beyond the point where the canal enters Lancashire and Yorkshire, near Colne. The length from Leeds to the summit-level at Greenfield is 41 miles. This great undertaking was forty-six years in progress, and was not completed so as to allow vessels to pass from Leeds to Liverpool until 1810.

The Market Weighton Canal is important both for the purposes of navigation and the drainage of the low levels through which it is conducted. It commences at a point called New River Head, near Market Weighton, in the East Riding of Yorkshire, and having a nearly straight course to the south, joining the Humber by a sea-lock very near the commencement of the Ouse and Trent, passing through Walling Fen, which contains 20,000 acres of land. It is supported by an acreage tax upon the occupiers of the lands drained by it, and the cost of the canal is about six million pounds sterling. It crosses an agricultural and manufacturing district in a beautiful and durable kind of brick, called the Walling Fen brick. It was made under an act of 1772, and was finished in 1776.

Mr. Whitworth.

The Ouse River Navigation is described among the communications on the previous page.

The Poolington Canal was formed under an act of the year 1815, for the conveyance of coal and lime to, and agricultural produce from, the neighbourhood of Poolington, in the East Riding, near the Welles. It commences in the river Derwent at East Cottingham, and runs nearly parallel with one of its feeders, in a circuitous north-eastern course, to near Pocklington. It length is about 25 miles, and it carries five locks.

Sir John Ramsden's Canal commences at the river Calder, at Cooper's Bridge, and runs south-west for about 34 miles to Huddersfield, with a rise of 93 feet. In addition to its importance as a link in the navigation, the island by the Huddersfield Canal, this navigation has been the chief means of raising the town of Huddersfield, which was built chiefly on Sir John Ramsden's property, to its present position as one of the chief markets for woollen goods in the county. The act for its formation was obtained in 1774.

The Ripon Canal is a short cut parallel with the river Ure, for connecting Ripon with the navigable part of that stream. The Rochdale Canal commences in the Calder and Hulhe Navigation, at Sowerby Bridge Wharf, near Halifax, and runs west by norh along the valley of the Calder to Hebden Bridge, where it turns with the river west by south, leaving the county of Yorkshire, where it enters Lancashire. [Lancashire, vol. xiii., p. 290.] It rises considerably on this part of its course, but does not attain its summit-level till after leaving the county. This canal is made of sufficient size to receive vessels capable of navigating the tides of the Humber, and in this respect is of great importance, that goods may be transmitted by it from Liverpool to Hull without change of vessel, a circumstance of great importance in the transmission of Baltic produce into Lancashire, and of the manufactures of Lancashire to Hull for use in the coal mines of Yorkshire.

The Selby Canal is a short cut connecting Selby, on the Ouse, with the Aire at West Haddlesey. It is alluded to in the account previously given of the navigation of the Aire-borough canal.

The Sheffield Canal, made under an act of 1818, commences in a cut communicating with the river Don or Dun at Tinsley, and pursues a course of a little more than four miles, nearly parallel with the Don, to Sheffield, crossing the river Don by the bridge at Attercliffe. It rises rather more than 70 feet, by eleven locks. This canal communicates, by a railway previously formed, with collieries in the parish of Handsworth.

The Stainforth and Keadby Canal, formed under acts of the years 1798, 1799, and 1804, commences in the River Don Navigation, near Stainforth, and proceeds eastward by Thorne into Lincolnshire, where it joins the Trent at Keadeby, crossing the county boundary near Crowle. Its total length is 147 miles, and contains the town of Doncaster. It crosses the county of Yorkshire, and passing through a very flat country, it has no lock, except at its junction with the Trent. By avoiding the shoals in the lower part of the Don, this canal affords a superior line of communication with Hull and the East Riding, as well as with Lincolnshire, to that by the Don and the Ouse.

The Thamet Canal is a short branch from the Leeds and Liverpool Canal to limestone-quarries near Skipton, formed by the Earl of Thame, under an act of 1773.

The River Ure Navigation is noticed under the river itself, and a part of it also under the title of the Ripon Canal.

Roads and Railways.—Marshall, in his 'Rural Economy of Yorkshire' (vol. i., p. 190, 290), mentions the very bad condition of the roads of Yorkshire within his memory, owing to improper modes of road-making and repair; but he intimates that considerable improvements had been effected before he wrote (about the year 1786), and mentions, among others, the road from York to Doncaster as a favourable specimen. A few years later, in the 'General View of the Agriculture of the West Riding of Yorkshire,' drawn up by Messrs. Reen, Brown, and Shirreff (pp. 36-57), he says: 'As the present direct communication is a great improvement on the number of good roads, and although that which was then different, chiefly from the deficiency of good stone for forming the surface, especially near the manufacturing towns; a circumstance which called forth the ingenuity of the road-makers in York and Leeds, to invent new materials of brick in lieu of harder materials. Owing to the frability of these materials and the great number of water courses travelling from town to town, some of the most important roads were in a very bad state; but great improvement had been effected in the exteriors of cities, and the country roads of the west, with the exception of the east, have continued to improve.'
roads and facilitated the employment of good stone from a distance. In this paper allusion is made to the paved foot-paths formed by the side of many roads, but which were also in some cases used as bridle-roads, on account of their being open and unobstructed. Many of the roads in the North Riding, those in the district of Cleveland especially, are very good, and there are numerous handsomely-bridged. Those in both the Eastern and Western Moorlands, but especially in the former, are narrow, steep, and rough, and in the East Riding the roads usually are. Wolds are inferior to those in the Levels. Those of Holderness, and in the vicinity of Howden, are chiefly formed of gravel from the sea-shore, but burnt bricks of irregular form, broken up to imitate stone, are still used in some parts of the wolds.

Of the roads of the North Riding the large proportion are merely pariahs-roads, and in the East Riding the proportion of turnpike-roads is still smaller. For the aggregate length of turnpike and other roads in the county and its several divisions, see the Table appended to the article ROADS, vol. xx. p. 37.

The great north road from London to Edinburgh, by Coldstream or Berwick, enters Yorkshire from Nottingham-shire at Bawtry, and proceeds in a tolerably direct course, but the north, inclines a little inward, by Doncaster, Ferrybridge, Wetherby, Boroughbridge, and Northallerton, to the border of Durham, near Darlington. A branch leading also to Edinburgh, by Carlisle, leaves this line at Boroughbridge, proceeds nearly parallel with it by Leeds, Wetherby, and aftershand turns westward by Greta Bridge, and enters Westmoreland near Brough; while another route from London to Edinburgh leaves the first-mentioned road at Ferrybridge, proceeds north to Sheeburn and Tadcaster, and then inclines north-west to York. This city is crossed by a north-western branch of the line, which, from York to Darlington, is less than 45 miles long, of which length upwards of 45 miles is in Yorkshire. It was opened for traffic early in the year 1841.

The Hebburn and Wentbridge Railway is a line about 74 miles, formed under an act of the year 1836, commencing at Hebburn on the coast of Durham, and proceeding northward to York, and thence to a branch line crossing that river and the Tees, with their several approaches, are among the most extensive engineering works of the line, which, from York to Darlington, is less than 45 miles long, of which length upwards of 45 miles is in Yorkshire. It was opened for traffic early in the year 1841.

The Hull and Selby Railway, formed under act passed in 1836, is said to be, considering its length in straightest and most level line in England. It crosses for the most part the parishes of Hedon, Lissett, and Barmston, and was propelled for the purpose of conveying stone from the quarries of Westbridge and Stainfleet to the city of Hull. The line is 20 miles long, and opened in 1838.

The Hull and Selby Railway, formed under act of the year 1830 and opened in 1834, continues the communication westward from the main mentioned line, for the most part on the same straight line, by Sherburn-in-Elmet, and the town of Selby, a distance from the line of nearly 30 miles. A little eastward of the town of Leeds the railway passes an elevated ridge by a tunnel of about 800 yards. The line is leased to the York and North Midland Railway Company.

The Manchester and Leeds Railway, the act for which was obtained in 1836, was commenced later in 1837, and opened throughout in 1841. Following the same course as the Rochdale Canal, this line enters Yorkshire near Todmorden. Of the several towns in this woollen district in the West Riding, and also between the West Riding and Lancashire. Of the railroads of Yorkshire it is unnecessary to particularize such as have been formed merely for communication with mines and quarries, for the most part in the hands of individuals, and without parliamentary powers; but one railway of this class, the first in the following alphabetical list, is inserted because of the peculiar interest attached to it as the first, if not absolutely the first, formed under the powers of an act of parliament, as well as being probably the first upon which locomotive engines were regularly employed. Excepting where otherwise stated, all these lines are worked by locomotive engines.

Branding's Railway, from the name of its constructor and proprietor, and sometimes, from the collieries with which it communicates, the Middleton Railway, and was formed under an act granted to Charles Brading, Esq. and others, persons, in the year 1758. It connects the Middleton collieries, about three miles to the south of Leeds, with that town; and on this road, about the year 1811, he introduced a kind of locomotive engine propelled by Mr. Blekinseed, which was propelled by a horsetail wheel working into a rack-rail. [Railway, vol. xii. p. 248.]

The Great North of England Railway, the York, and the Leeds portion of which was formed under an act of the year 1845, although the company was incorporated in 1843, commences by a junction with the York and North Midland Railway outside the walls of York, the same entrance to which is the only one by which the line enters the north by west in a remarkably straight and level line along the great central valley of the county, passing near Easingwold, Thirsk, and Northallerton, to the Tees at Croft Bridge, whence the route is continued northward and across the Stockton and Darlington Railway.
England, without any gradient of steeper inclination than 1 in 150, a slope which is conveniently surrounded by locomotive engines. A branch line is being formed to Huddersfield, and a railway from Leeds to Bradford has been projected, which, if continued to Halifax, would form a much shorter though less level communication between Leeds and the western portion of the line. By a short junction-line now forming at Manchester, this line will be brought into communication with the Liverpool and Manchester Railway, and communication between Liverpool and Hull, through the York and North Midland, Leeds and Selby, and Holl and Selby railways.

The York and North Midland Railway, which, in common with the preceding line, was laid out by Mr. George Stephenson, enters this county from Derbyshire near Beighton, a few miles south-east of Sheffield, and proceeds northwards to Masham, near Rotherham, where it crosses and communicates with the Leeds and Rotherham Railway. The works proceed northwards by a very winding course to the junction with the Manchester and Leeds Railway at Normanton, and, a little farther on, those of the York and North Midland Railway, near Methley, from which it turns north-west to the more southern line; and thus the tunnel, from this long tunnel at the head of the Don valley, the railway proceeds along the course of that river, first eastward to Penistone, and then south-east from that town to Sheffield. Part of this line towards the Manchester terminus has been opened, and the eastward branch of the tunnel is not yet finished. A branch is proposed from this line to Penistone, by Barnsley, to the North Midland line, which would afford a new route to Leeds, rather shorter than that by the Manchester and Leeds Railway, and would form a better line than the former for goods from Sheffield to Penistone. Emerging from its Sheffield terminus, along the valley of the Sheffield to the North Midland at Chesterfield, which would greatly shorten the distance between Sheffield and the south. An act was passed as early as 1821 for a railway between Derby and Manchester, but nothing has been executed. The Sheffield and Rotherham Railway was projected in 1834, but the act was not passed till 1838, in consequence of the strenuous opposition of some interested parties. It joins the line from Sheffield, which ascends north towards Masham, and Rotherham, communicating with the North Midland Railway, and, by a branch, with the Gresborough collieries. This line, which was opened in 1838, is about 4½ miles long, and the Gresborough branch is about 1½ mile.

The Stockton and Darlington Railway belongs chiefly to the county of Durham [DURHAM, vol. i., p. 206], but, under an act of 1828, the company formed a branch or extension from Stockton, crossing the Tees by a suspension-bridge, and thence through the hills, strengthened from beneath, and proceeding eastward to the shore of the estuary of the Tees in the township of Middleton or Lowerthorpe, where it has been the means of establishing a port of considerable trade, and some industry. The line between Middleton or Middlesbrough and Middlesbrough branch is about 4 miles long, and the Cleveland extension 1½ mile.

The Whitley and Pickering Railway, a line of about 24 miles, worked by horse-power, except on one or two places which the engineer regarded by gravity alone, was formed under an act of 1833 and opened in 1836. From Whitby Harbour the line proceeds south-west for about 6 miles along the valley of the Esk, which it crosses by a bridge of masonry, and then runs northwards through a short tunnel into the romantic vale of Goathland, after which it passes along Newton-dale, nearly in the course of the stream called Pickering Beck, to the town of Pickering. This railway has a single track, and was formed for the small sum of £400 per mile on an average. Besides passengers and goods, the line conveys much mineral produce, especially stone from the quarries of the Whitby Stone Company, which are connected with the line by a short branch near the tunnel. A beautifully illustrated volume, descriptive of this line and the varied scenery through which it passes, was published in 1836.

The York and North Midland Railway, formed under acts passed in 1836 and 1837, and completed in 1840, was originally intended to be a York and Leeds line, but was modified in consequence of the design of the North Midland Railway. It runs northwards within the limits of Yorkshire, passes through the city wall through an archway common to this and the Great North of England Railway, which joins it outside the city, and then proceeds south by west to Sherburn, crossing the river Wharfe by an extensive bridge. At Sherburn a branch of about a mile curves eastward to join the Leeds and Selby Railway, which is now leased, but is about to be purchased by the proprietors of this company, at Milford, 144 miles from York, 131 miles important sunk. It is 2½ miles long, the line proceeds southward under the Leeds and Selby Railway by a bridge, and south of the point of intersection is a second branch curving north-eastward towards Selby.

The line then turns south-west, with some heavy earth-works, and immediately beyond the points of the Leeds and Selby Railway, which actually joins the North Midland Railway by two branches, one of which crosses the Calder and turns towards Leeds, while the other inclines southward, and joins the North Midland at Allofts. The main line, which is remarkably short, is 14 miles, and from this point to Allofts, 117 miles more. Besides forming a link in the line of communication from London to Newcastle and Edinburgh, the southern portion of this line, from Milford to Allofts and Knaresborough, forms part of the new railway connecting Leeds with Hull and the west, and also a better though somewhat longer route between York and Leeds than that by the Leeds and Selby Railway. Branches are proposed to Scarborough, and the Whitley and Pickering Railway, and to the Knaresborough and Harrogate Railway.

Manufactures.—In its industry, as well as in other respects, Yorkshire is an exceedingly varied and interesting portion of the kingdom; and the West Riding forms one of the most important manufacturing districts in England, and a greater variety of manufactures are carried on at Kirkstall, and in some other parts of the West Riding, of which Lewis mentions Wensleydale and Masham. Flax-spinning, as observed by Mr. McCulloch, in his Statistical Account of Yorkshire, pp. 368-369, is carried on to a greater extent at Leeds than anywhere else in England. Extensive iron-works, which formerly enjoyed considerable celebrity, were situated at Rotherham, and there are others in the neighbourhood of Bradford; but, according to the work just quoted, which is the principal authority for this part of the article, the iron-works of Yorkshire, if not actually declining, are making but little progress. Their total produce in 1838 was estimated at about 35,000 tons. For a further notice of these see DURHAM, vol. i., pp. 317, 347, and p. 318. The manufactures of hardware and cutlery at Sheffield, and in the district surrounding that town, are very extensive, and in some departments exceed those of Birmingham. In cutlery particularly, the Sheffield establishment, and it maintains a high reputation in other branches of manufactures, which are noticed under SHEFFIELD, vol. xxvi, pp. 368-369. The manufactures of the North and East Ridings are of comparatively small importance, and are confined, in the principal county, consisting of freestone, limestone, coal, iron, copper, and lead, are most extensively used in the West Riding. At Wickersley, about four miles east of Rotherham, several thousands of granite single-stone millstones are made for the field manufacturers, some of which are sunk to 120 feet in diameter. The coal which occurs in
of the manufacturing prosperity of the district, is found chiefly in the vicinity of Leeds, Sheffield, Bradford, and Wakefield. A small woollen district exists near Morley, the chief of which is concerned with the manufacture of cloth. This district is of a smaller extent than those of Leeds, Bradford, and Wakefield. In the several articles on those towns will be found particulars of the respective branches of which they may be considered the centres, and especially under Leeds, Bradford, and Halifax, the history and statistics of the woollen manufacture are treated at length. 'Cloth is,' observes Mr. M'Culloch, 'the chief article manufactured in this district, the greater part being made in the neighbourhood of Leeds, Wakefield, Huddersfield, and Saddleworth. Leeds, in particular, he processes a grand mart for all white and broadcloth flannel. The former, which are usually called mixed cloths, are made wholly of dyed wool. The mixed-cloth manufacturers reside partly in the villages belonging to the parish of Leeds, but chiefly at Morley, Gildersome, Spring Grove, Huddersfield, Dingley, Ossett, Wakefield, Calverley, Ecclesfield, Idle, Buildon, Yeosum, Guiseley, Rawden, and Horsforth, in or bordering upon the vale of the Aire, principally to the west of Leeds; and at Batley, Dewsbury, Ossett, Horbury, and Gomersal, and west of the valley of the Calder. Very few mixed-cloth manufacturers are to be found to the east and north of Leeds, and are but few in the town itself. White cloth,' according to the same authority, 'is principally manufactured at Ossett, Wakefield, Kirkheaton, Dewsbury, Batley, Birstal, Hopton, Mirfield, Ecclesfield, Cleckheaton, Bowling, and Shipley, a tract of country forming an oblong belt through the vale of the Calder from the vale of the Aire, beginning about a mile south of Huddersfield, leaving all Huddersfield about a mile to the left, terminating at Shipley on the Aire, and not coming within less than six miles of Leeds on the right.' Though generally distinct from each other, the districts of the mixed and white cloth occasionally, as will be seen from the above description, run into each other, especially upon their southern and south-western extremities. Flannels and baizes are the principal articles made about Halifax, and the chief district for blankets and flannel, and flannel and baize, within which district, it is stated, is largely practised at Bradford, where also, as well as at Halifax and Leeds, stuffs are manufactured. In and near Huddersfield are made narrow cloths; and Saddleworth produces kersey and worsted cloths nearly equal in quality to those of the west of England. Wakefield also is chiefly celebrated for its woollen market and the skill of its cloth-dyers. Near Batley and Dewsbury are establishments called shoddy mills, for manufacturing yarn from woolen rags and refuse goods, of which considerable quantities are imported. A little new wool is usually added, and the yarn is made into a coarse kind of cloth which is used for padding and similar purposes. From the nature of its manufactures, consisting of baizes, flannel, kersey, and broadcloths, Rochdale may, though situated in an extensive country considered to belong to the woollen district of Yorkshire.

Though it is difficult to estimate the proportion exactly, M'Culloch conceives that the woollen manufactures of Yorkshire form fully three-fourths of those of the whole kingdom. From the Returns of the Factory Inspectors it appears that there were, in 1834, 1102 woollen factories at work in the whole of England, employing 65,461 persons, while those in the West Riding alone amounted to 261,732 persons. The employment for the year accounted for the great cloth-halls are given under the towns to which they belong, where will be found details as to the mode of conducting the business. Much cloth is however produced and sold without passing through the halls. For a long period until the 18th century, Acts of Parliament were in force, under the name of Stamping Acts, for the purpose of preventing fraud in the measurement of cloth, and from the year 1725 to 1813, annual returns were made of the quantity of cloth milled at the several fulling-mills of the West Riding. In the first of these years the number of pieces of broad-cloth amounted to 261,732, and in 1813, the length of which amounted to 5,515,755 yards. Since the first year for which the returns embrace names, the number of pieces of that kind was 14,485, and in 1813 it had increased to 145,805, the length of which amounted to 50,015,725 yards. Since the period embraced by these returns, the manufacture has continued to increase, with even greater rapidity, as can be ascertained from the increase in the number of factories and the imports of foreign wool.

For a time the manufacture of the woollen cloth produced in Yorkshire consisted of the cosier kind of cloth; but the manufacture has been so greatly improved that Yorkshire clothes are no longer looked upon as inferior to those of other districts, while the fineness of cloth made in the West Riding are excellent. Every branch of the woollen manufacture is at the present (1843) in a state of activity, and in some branches it is difficult to obtain a sufficient supply of hands. Some extensive are the operations of the principal manufacturers, that one house alone, at Halifax, employed between 5000 and 6000 individuals, to whom nearly one-half are engaged in the various branches belonging to the firm, while others perform their work at home, in their own premises.

The extent and prosperity of the manufactures in the West Riding, by opening markets for produce, extends the most beneficial effect upon the agriculture of the district. Agricultural land is not only improved by the manufactures, in an agricultural point of view, but from its extent and the variety of soils and differences of climate which are found there, it is absolutely necessary to force its industries to spread and its manufactures to the north, for the sake of the agricultural industries of the county of Durham. The south-west, while the West Riding and Westmoreland possess the West Riding, the length of the Riding from east to west 30 miles, and from north to south 47 miles; it contains 1,500,000 acres of cultivable land, so that at least or at least was so at the Agricultural Survey of 1843. Part of this has no doubt been brought into cultivation and sand, but there are still extensive moors and mountainous, which are scarcely capable of much improvement.

The soil on the coast is mostly a brownish clay, of a loamy incumbent on a clay or on freestone; and in new valleys west of Whithby the soil is a rich deep loam. The valleys are 30 miles by 15, with 30 miles by 15, and are penetrated by many cultivated valleys more or less fertile. The hills are covered with long grass where the freestone does not crop out and present a bare rocky top. The valleys and meadows have not the same dreary appearance as the country towards the south, where it is brown with ling there are sweet grasses interspersed with it, which are cattle and sheep soon find out. The farmhouses are generally so conveniently situated for the convenience of the cottages, and are often inhabited in villages at a distance from the fields. Where new buildings have been erected on the inclosures of common land, they are better situated, and save the farmer much expense in the carrying home of his crops and in manufacture. In 1818, various Acts of Parliament were in force, under the name of Stamping Acts, for the purpose of preventing fraud in the measurement of cloth, and from the year 1725 to 1813, annual returns were made of the quantity of cloth milled at the several fulling-mills of the West Riding. In the first of these years the number of pieces of broad-cloth amounted to 261,732, and in 1813, the length of which amounted to 5,515,755 yards. Since the first year for which the returns embrace names, the number of pieces of that kind was 14,485, and in 1813 it had increased to 145,805, the length of which amounted to 50,015,725 yards. Since the period embraced by these returns, the manufacture has continued to increase, with even greater rapidity, as can be ascertained from the increase in the number of factories and the imports of foreign wool.
a farm, he expects to find the buildings in good repair, and
engages to keep them so, which condition is not often
strictly adhered to. The cottages for labourers are small
and mean, and generally consist of two small rooms on the
ground floor, which is often damp, and consequently un-
healthy; and the lodgings are bad. The farmer as to his
labourers should be comfortably lodged, and have a certain
extent of garden-ground to raise vegetables for his family.
He will not then be tempted to steal the turnips and
cabbages on the farm. In the North Riding of Yorkshire, as in the
rest of the county, are of every imaginable size, from 50 to
1000 acres and more. It is generally found that farms
from 300 to 500 acres, occupied by intelligent tenants with
much labour, make more profit to the owner than those of
the greatest proportional small. Farms are usually occu-
pied by men who have little more capital than their stock,
even if that is their own, free from debt, and consequently
have not the means, if they had the inclination, to bring
their farms into a high state of cultivation, feeding cattle
and purchasing bones, oil-cakes, and artificial manures, on
which high farming depends. When a farm is too large, it
requires too great a capital, and every portion cannot so
well be attended to by the farmer: we mean those which
are remote from the farms, and which are necessary and in-
valuable to the tenant, such as not to plant above one or
two acres of potatoes, as if on a well-managed farm pots-
apes were not one of the most profitable crops; and their
introduction into the regular rotation on light soils would
be most beneficial. If there must be restrictions, let it be that potatoes shall not recur above
once in eight or ten years on the same spot. The exact
rotation of crops is likewise laid down in some leases, which
entirely precludes any improvement, and takes from the
farmer the advantage, but for us it must remain. The rotation
is, as we think, a consequence of the introduction of
improved rotations of crops.

The most common rotation on heavy loams is, fallow,
weat, beans and peas mixed, oats, which, if the beans
are kept after the fallow, will be profitable and
rotation, but otherwise too exhausting. The hay produced
on the grass land, and given to cattle in winter, may
in some measure give a sufficiency of dung to keep the land
in heart. On the gravelly loams the Norfolk course is
preferable, turnips, barley, leguminous, grain, and
wheat. Sometimes peas take the place of the
clover; they might be profitably introduced between grass
seeds and wheat, as this last does not give so good crops
after ryegrass as after clover; and the introduction of
peas is according to the eight principles of the succession
of crops. A curious alternation is practised by some
on light soil, which is, turnips and barley, the turnips fed off;
and it seems to be a very profitable course. How long it
will succeed we will not pretend to determine; but, as
with wheat and beans on good loams in Kent, with a care-
ful destruction of weeds, it may succeed for many years.
If the turnips continue good, it is a very profitable course.
The only manured used for the turnips is lime: bones would
be the most economical. The manure is spared for the
grazing land, a most preposterous arrangement. In the very rich soils of
Ryedale several crops of oats are often taken in succession with
much success; but, like all very rich soils, they will do so
for a time only, and at the expense of the heart of the land,
and all the future crops for generations to come. It is
literally eating up the capital, which should produce a
good interest for ever. An old and bad course on heavy
land is still occasionally met with in Cleveland, which is
fallow, wheat, oats, and clover left two years: by merely
transposing the two last, or taking oats after the fallow
and wheat after the clover, the same crops would give a greater
return and leave the land clean. Oats after wheat must
not be taken in fallow, or the clover cannot possibly
thrive in foul soils.

There is no part of England where lime is so much used
on the land as in Yorkshire; but however advantageous
this may be on sand-loams, it must evidently be thrown
in too large quantities on the heavy soils, and by
itself, without the aid of dung, it cannot be made
profitable to bear crops, and exhausting it of its natural organic
components. On land which has been long in grass, and where
the soil contains little calcareous matter, lime is extremely
beneficial; but upon the large areas of Cleveland it is
unwise. When dressing of rich dung be given at the same time, it does
more harm than good. Wheat is generally sown in the
first week of October, although some continue to sow it
in open weather till March, as the turnips come off and
have good crops, if the weather is dry. The corn, when not
mown, is reap'd with the sickle generally by women; the men seldom reap but the
tie up the sheaves, one man tying for three women; sometimes a boy makes the bands for him. The sheaves are set up in tens, two sheaves being turned over them as a protection against the wet. It is usually done in the morning, but it must be done in the evening by the last light of the day. This may be advisable; but if the weather is fine, it is much better to let the ears have the advantage of the sun and morning dew; even a few showers will not hurt the corn after it is in the lowest stage. The best wheat is grown in Cleveland, and ryegrass is more abundant than those in Ryedale, where the turnip system is more general, instead of fallows. Much wheat is exported from the ports of the North Riding, chiefly to the manufacturing districts, besides what supplies the local consumption; but, of late years, corn and rye meal were the chief food of the labourers, as well as meslin, that is, wheat and rye sown together, which makes good wholesome bread. On the good light soils as much as six quarters of rye per acre has been grown. The barley of this Riding is not particularly fine, nor the crops large. It seems as if the land was better suited to rye and oats: the reason of this it may be more difficult to explain; it arises probably from the natural texture of the soil, more than from its composition. The quantity of barley sown is usually ten pecks, and the crop averages four quarters per sown acre. Ryedale is remarkable for its fine oats, which are usually sown on the turnip land, or on the grass land when ploughed up. The sort is generally the Friesland oat, and the quantity of seed is then shallowly sown per acre. On some of the best lands they sow as much as eight bushels, which appears enormous, and probably diminishes the crop by weakening the stems, which grow too coarse. The idea is, that on good land, the more seed that is sown, the better and sooner it will be made, which is a necessary consequence. The farmers are particular in getting a change of seed from Holland every four or five years. Oats are sown in March and April, the earlier the better, if the weather permits. Eight quarters per acre is an average crop of good land. The oats are either threshed out soon after harvest, as new oats make the best oat-meal, to which purpose they are chiefly applied. A quarter is supposed to weigh twenty-four stones, and is often sold by weight, instead of measure, at this rate.

The soil is very well suited for seed on the best lands, and the preparation is often by ploughing and burning grass lands, which is sure to secure a crop. The seed is sown in July or August, and the plants thinned out or transplanted in October. Where there is a great breadth of rapeseed, the plants are raised in small beds, and transplanted with the plough. A furrow is made and the plants are placed a foot apart, leaning on the furrow-slice turned over; when the plough returns, it covers the roots, and the plant is fixed; it should be turned so that a woman treads by the side of every plant to fix it; a shower of rain renders this operation superfluous. Rape is usually ripe in July, and threshed out on a cloth in the field, by much shedding of the seed is saved. It should be burnt as soon as it is ripe, the cropings are a kind of festival, like hop-picking in hop countries, and draw together many labourers and more idlers; but the work must be finished rapidly in so precocious a climate, for a wet day would spoil all. If there is much seed, great care must be taken that it do not heat too much in the heap. This inconvenience is avoided where the rape is stacked in the straw for some time before it is threshed; but then it must be very carefully handled in the stacking and carrying, or much seed will be shed and lost. It is in this way that the rape seed is best beaten, as early as possible, a cloth being laid under the part which is beaten. This beats out the seeds; they would otherwise soon be devoured by the birds, which are very fond of them. In carrying rape a cloth is spread over four poles, one at each end, the wine, or pole, as it is called, is beaten on; the cloth is laid on the sand, or other hard ground; there are also light barrows with cloths over them, to carry the sheaves to the wagon or stack. The grass and refuse of the rape is excellent fodder for the cattle in winter; it is therefore waste to burn them in the field, as some do. The crop usually averages the same as wheat; but the price fluctuates greatly. To be a profitable crop, it should not be less than the price of wheat.

Potatoes are grown on grass land near and burnt, or there is a manner of roasting them in trunks or three or four quarters having been first baked with great care in a close oven in spring; but now the usual cultivation of this root on the Northumberland plan is generally adopted, with a very careful preparation and manuring.
by these are raked together, and either stacked at once, or, if there is a large quantity, and the weather is pre-
vailing, they are collected into large heaps, where they are blown slightly before they are removed, to avoid the stink which should be avoided if possible, as some of the bottom of the cock is always more or less damaged by the moisture rising from the ground; besides, being considered safe in these cases, it is often left too deep, and sometimes no sufficient interval of dry weather occurs to allow them to be carried till over, nor is this done where they are to be stacked in good order. The dairy and fattening cattle and sheep are usually sent to the pastures about the 12th of May, till October, when they are removed to the after-
erness; the dairy cattle are fed with lea-shorn sheep, and kept bare all winter—a very practical system, which improves the land and encourages grass. All pastures should be mown once at least in three or four years, to improve the grass and destroy rank

There was once a fair proportion of timber-trees both in the woods and hedge rows of this Riding; but they have been much thinned, and at present the quantity is not worth 20d. or more, which pays well for her resounding in the dairy districts, being useful for butter and and other dairy implements which require a white wood.

The short-haired breed of cattle is the prevailing sort all over Yorkshire, and of this there are some varieties. The names thereof are: (1) the short-corned Leeds, October 10 (cattle); (2) the name of the Tees-water breed, in England are the Holderness breed. They originally came over from Holland, and are very profitable where the pasture is good, but on poorer land they soon degenerate. Oxen are kept in Yorkshire in winter, 15, October 15, November 10, 11, and 12, but the Western Leeds the cattle are smaller, and on the pastures of the West Riding and Westmorland the horned breed is very common. A cross of the two breeds has been praised by some, but it is doubtful if anything can be done in this direction. The Holderness breeds, being close confined, scanty, and giving much milk, although not so rich in cream as some of the smaller breeds. A fine heifer with a calf by her side, or ready to calve, or to be turned out, is a very desirable animal, but there is no such thing as a milk cow in Yorkshire. The dairy cows have a great deal of milk, and sometimes it is not to dry the old milk in prime time before calving, or when they are put up to fatten. Salt pepper given to cows, an ounce or more at a time, after breeding them, is of great importance. They have a strong appetite for milk, which they should at first be milked only once a day, taking some milk in the udder at each milking, and they should only be relieved when the milk seems to accumulate, and might cause infection in the udder.

The breed of horses in Yorkshire is quite coarse, being fed at 30lbs., and even 40lbs. per quarter at three years old, and producing 10lbs. or 11lbs. of wool, but the breed has been much improved by crosses from the Clydesdale breed. The wool and carcass have both been much improved by it. The sheep on the Western Moorlands are horned, with grey faces and legs; and many of them have a black spot on the back of the neck: their fleece is coarse. The breed of horses all over Yorkshire is well known and highly appreciated. In no country are so many valuable horses as in Yorkshire, and they are of the best breeds, and fetch great prices. For carriage-horses, Cleveland horses are in high repute when they have some size and age. In the fields of the Eastern Moorlands and on the coast moors, there are many sable horses, and the larger Yorkshire horse. Large numbers of farmers buy colts and yearlings at 20s. or 30s. per annum, and work them moderately till they are six years old, when they are sold for carriage-horses or sable, by this means they often have all the work done for little or nothing, the improved price paying for the expense of the horse. Mares are used generally for farm work, but they are made to give foals very early. The colts are worked till foaling, and aged about five weeks after the foal is ridden the team or the horse when of sufficient age. They generally drop in May, and are weaned in October, when they can live as the pastures. The practice of making up horses for sale is too well known to need a description. Yorkshire farmers are notorious for their art in hiding defects in horses; but as this is well known, they have generally taken precautions, and have good advice if he is not skilled himself: if he is ignorant and conceited, he will probably be taken in and thus be lost to Yorkshire pigs and horses are celebrated, but it is not in this portion of the county that they are the best. We will notice them in the other Ridings.

The markets and fairs in the North Riding are as follows—Askirgth, Thursday, May 11, first Thursday in June, July 13, September 19, October 16, November 29, and December 26; Bedale, Tuesday, Whitsun Tuesday, July 5 and 6 (cattle), October 10 and 11 (cattle), Tuesday next after Christmas (cattle); Brompton, November 12 (swine and horses); Cayoos, August 23 (cattle and sheep); East Ayton, July 5 and September 25 (cattle); Reton, Tuesday before Whitsun Tuesday, before May 11, September 5, and Tuesday before November 22 (cattle); Guisborough, Tuesday, third Monday and Tuesday after April 11 (cattle), August 20 (cattle), September 19 and 20, and first Monday after November 11 (cattle); Hawes, Tuesday, Whitsun Tuesday and September 28 (cattle); Helmsley Black Moor, Saturday, Saturday before Palm Sunday (cattle), Saturday before Whit-Sunday (cattle), Thursday before Palm Sunday (cattle), Thursday before Palm Sunday (cattle) and Sept. 11 (sheep); Laybourn, Friday and Monday before Whitsun Tuesday, first Mondays in May, October, and December; Malton (New), Tuesday, Saturday, Monday and Saturday before Palm Sunday, Saturday before Whit-Sunday, Saturday before Palm Sunday, Saturday before Whit-Sunday, and September 17, 18, and 19 (cattle); Middleham, Monday, November 6 and 7 (cattle); Northallerton, Wednesday, February 14, May 15, September 5 and 6, October 3 and 4 (cattle), and Swinton, second Wednesday in October (cheese); Pickering, Monday, September 25 and October 15 (cattle), Tuesday before Palm Sunday, Friday next after before May 12, Friday before August 24, Friday next after before November 22; Richmond, Saturday, Saturday first Thursday in July, and September 14 (cattle); Scarborough, Tuesday, Thursday, and Sec. Thursday, Bramley, July 15 (cattle, blue, &c.); Stan- ford Bridge, December 1 (cattle, &c.); Stokesley, Saturday, Saturday before Trinity Sunday (cattle); Thirsk, Monday, Shivere Monday, April 6, August 5, October 19 (cattle), October 20 (sheep), and Tuesday after December 11 (cattle, &c.); Tollerton, August 26 (cattle); Topcliffe, July 17 (cattle), 18 (sheep); Whitby, Saturday, September 6, November 22; Yarm, Thursday, Thursday before April 6, Holy Thursday, August 29., 30, 31 (cattle), and September 20 (sheep).
tricts nearer the sea, although the frost and snow are of more continuance in winter. The sea air tends to keep a more regular temperature, cooling the summer heats, and moderating the cold frosty winds in winter. Chalk forms a principal portion of the substratum of the southern part of the district, and in several places is a bold lofty front to the north of this Riding. It occupied a great portion of the centre of this Riding from the Humble to Flamborough Head.

The soil of the Wolds is a light friable calcareous loam or chalk rubble, which covers the solid mass of chalk. There are fints in the soil, but not of such a size and in such quantities as in other chalk districts in the south. On the banks of the Humble there are above 14,000 acres of wap land, a stiff clay of extraordinary fertility. [Wap land is a proportion of the land in the north of England, often sequestered and managed as a common by the owners of the contiguous land.] The great market for this game is often kept with sow-thistle and other rank weeds, which abound in such soils. No wheat can be expected after such a crop, and a fallow is indispensable. Spring tares are sometimes sown with the beans, in the proportion of half a bushel to three quarters of a bushel of beans. The seeds are usu ally kept by the sieve when threshed. This mixture is good when beans are sown to be cut up green, to give the pig and cattle; a very excellent practice, which ought to be more common on heavy soils. The weeds then are chaff, and have neither to be burnt nor ploughed up. The ground may admirably be prepared for wheat by a bastard fallow, as is generally done.

Rape is extensively grown in Holderness both for feed and for seed; in the former it is generally succeeded by wheat; in the latter, by oats. The time of sowing is about the middle of June; the quantity of seed is about a peck per acre. Rape and cole seed are often sown, but the rape seeds up straight stalks, and a late sowing is better than a good fallow. The best oil is made from the Rape. If rape be sown early, rape seed the same year: cole is a decided biennial. 

Hedon, Patrington, Sunk Island, and other rich wold lands, much cole-seed and rape-seed are raised, the latter, in fact, is almost the support of the population of the Wolds; the latter is the place where the sheep-walks on the Wolds rape is often successfully grown; but it may be doubted if so exhausting a crop be not too much for thin poor lands which have not the temporary richness produced by the roots of grass, and have no ready exit from the Rape. The Rape will be restored by manure from the distance of the first pastures from the homesteads and villages.

Sainfoin has been introduced wherever the inclination is to make a stand, in which it is an invaluable plant. The more actively grown in Holderness the more uniformly in Sussex—Agriculture of, to which we refer. Potatoes are very extensively cultivated in Holderness and Hordenham. The potato grown upon the wold lands are preferred in the large market towns, and are used more extensively to make fresh and dried sown for the potato market. The best have been long known by the names of Red-noose kine, Flat white, Purple kidney, and Cape kidney; the best top and Ox noble are very productive, but better suited to feed cattle with than for the table. They are cultivated to a great extent in Holderness. Buckwheat is advantageously grown in the sandy soils, and it is extensively grown in October; it draws late from the soil, and is an excellent amendment of weeds, which makes it a good preparation for turnips.

In the East Riding the proportion of grass lands in farms is much less than in the other Ridings. The grass pastures have been ploughed up, even on the Wolds, and those only which lie low along the rivers have been left for permanent meadows. The salt-mashes along the sea are very useful, especially to recover horses which have been over-worked; sheep likewise get fat on them after the harvest. The effect of the salt-water has been once recovered from this saltpayrty, they take rapidly.

There is here little timber in this Riding, either in woods or hedges, in this mode of cultivation. The ground is covered by the rich alluvials soils and the tenants and proprietors have generally been wise enough not to plant in hedges or rows. Some plantations have been formed on the Wolds, but they contain little useful timber.

Dry ground and the heavy soils of this district are barren; they were done in Holderness and other flat and low parts of the Riding, by which low and marshy grounds have been rendered fertile. Works have been erected at great expense under the authority of several acts of parliament, from 1727 to the present day. In the district of the Wold there are two levels, the one extending from Escrick to Barnham and containing 2130 acres, and the other from the same point to Wilscumme near Hull, containing 10,000 acres; amounted already to 135,000 acres, the interior which is barely repaired by the improved value of the land drained.
This implies some want of care and economy in the com-
misjioners, and something like jobbing in the contractors.
The drainage of 10,500 acres, called the Herford and Der-
vert drainage, part of which is in the East Ridings, cost
£12,942, or about 4£ per acre only. This pays the prov-
ors 21 per cent. on their outlay. Other less extensive
improvements have been executed, much to the improvement
of the country.

Near the sea-coast, chalk or sea-wood is very extensively
utilised for coaling; and after a storm the farmers' carts may
be seen busily employed at low water to collect it. It is
used in hedges, where it soon ferments, and, as soon as
convenient, is carried on the land; if left to rot, it would
seldom if ever be used. The former it is carried
in the land the better. It is excellent for turnips.
Bone-meal is now extensively used on the lighter soils, and many
manures are annually imported from the Continent into the
west of Hull for this sole purpose.

Cattle have been mentioned before, and

some other breed is found in the East Riding.

They are evidently of Dutch origin, perhaps through Hol-
lands, where they have also been introduced from Holland.

A different breed has been bestowed on the breeding of the

sea-board, and the next finest livestock which are of some and better proportions; whether the quantity of milk
increased, is not quite so sure; but the fatting qualities
are of so much importance in a district where breeding and fatting stock is generally preferred to the

rest of the country.

On the rich pastures the improved Leicester breed of

sheep is found the most profitable; on the Wolds the

Dorsets have been introduced with great success; and

these have been attempted, but, on the whole, the pure

Lincolnshire is the best.

No part of England produces so fine and valuable

wools as the East and North Ridings of Yorkshire. We are

mentioned the Cleveland bays. The introduction of

these into the country, and the land districts have been

sharply at high prices; but for the carriage

they are still preferable the pure Cleveland bays without a cross.

are compact, hardy, and of good courage, and can

have a hard day's work better than the half-bred horses,

the Lincolnshire, which are bred in a few places only.

These have been attempted, and which must be altogether

considered, is that with the large Lincolnshire hairy-legged

or-bears. This is quite incongruous, destroying the very

skin in which the Cleveland bays excel, which is the ab-

sent in the latter. The small figures on the back, the

real family, and the next best love which are but

jet black, shining, and smooth appearance of the skin in

the fetlocks gives them. The agricultural labourers

are well off in general in the East Riding; they often

and with the farmers, and are at work early and late.

If the following are the fair and market days in the

West Riding of England:

The following are the fairs in the East Riding:

Altrincham, Sept. 4; Beverley, Thur., Feb. 26, Holy
Thur., July 5, Nov. 6, Wed. before April 6, or on the 6th,
Wed. before May 13, or on the 13th, Wed. before Sept.
4, or on the 14th, Wed. before Dec. 25; Bransbury-
don, Dec. 13; Bridlington, Mon. bef. Whit-Sunday, Oct. 21;
Telford, Feb. 14, Aug. 2, Sept. 26, Nov. 17 (a market for fat
sheep every alternate Monday); Hornsea, Aug. 12, Dec.
11, Feb. 26; Hudderton, Jan. 7, June 17, Dec. 9, Feb. 26,
Thurs. after July 11, Oct. 2 (a great fair for horses
and cattle); Hull, Oct. 11 (horses); Hummubury, May 6, Oct. 29;
Kiln, Aug. 21, Nov. 12; Little Driffield, Easter-Monday,
Vindemia, Aug. 20, Sept. 19, Oct. 18, Driffield, Mon.
and Tues., Aug. 21, Sept. 19, Oct. 18, Mon. and Tues.,
Jult 17, Aug. 21, Sept. 19, Oct. 18, Thurs., 11th, 12th
of March, 3rd, 8th, 13th, 18th, 23rd, 28th of March,
8, July 18, Dec. 8; Pecklington, March 7 (if leap-year,
March 6), May 8, Aug. 5, Nov. 8 (large fairs for sheep
and cattle); South Cave, Trinity Monday; Stamford
and Grantham, Easter-Monday; Spalding, Trinity
Market); May 14, Sept. 17 (the largest sheep-fairs
in the north of England.

The West Riding of Yorkshire is situated nearly in
the centre of the kingdom, but, from its numerous rivers and
its extensive Canals, the east and west, the

in the east and west, and as it is separated by the river Ouse. The coun-

ties of Nottingham and Derby are on the south, and on the
west are those of Lancashire, Chester, and Westmoreland.
The North Riding forms its northern boundary. It is 56
miles long from east to west, 48 from north to south, and
contains about 4,100,000 acres of land.

In so great an extent the soil and climate naturally
vary. It is in general dry and healthy. The eastern and
northern portions are similar to the Ridings so situated, while the west parts of the moist and hilly nature of the

Atlantic. We give, therefore, a significant account of the

agriculture of the North and East Riding, that we shall

only observe that a great part of the West Riding is in pasture,
the arable land being chiefly found on the

northern and eastern portion, where it is cultivated much
in the same manner as in the

Holland, An Agriculturist, May 17.

ingleston, Novem-

r. Robert Brown of Markle, to which we must refer

for particulars.

As grazing is well understood in this Riding, much cattle
is purchased to be fattened here, but not many are bred; conse-

sequently a much greater variety may be observed in the

stock than in the other Ridings. The manufactures, which

have rapidly sprung up, cause a great demand for

the butcher's meat, as a great encouragement to the grazier.

The grass will naturally fatten an ox in summer, which for-

merly would have been considered as quite ripe for the

butter; but with the addition of turnips and hay in au-

"umn they are made very fat, especially the

linseed cakes, which is sometimes succeeded by oatmeal

and hay for the last 10 days, in order to avoid the flavour

which some very delicate palates detect in beef fed with

oily food. Many hogs are fattened in this Riding, the hams

are cured for the London market, and other

parts are delicately disposed of among the manufacturers, who never

find bacon too fat. This riding was formerly better wooded

than the rest of Yorkshire; but the forests have been de-

severely cut, and cultivated to

satisfy the demand for oak and ash of small size for the

use of the mines and collieries.

Much land in the Riding is fit for little else than planting

firs and larch, and where the

latter wood has thriven considerable profit has been made

by the well managed plantations. You must

lay out on his land, and, having no rent to make up, is

satisfied if his farm feeds him and his family, which it often
does but scantily, after very hard labour, such as a

tenant holding a large farm would disdain to submit to

for particular.

The properties and farms in the West Riding are

generally smaller than in the other Ridings, and there are more

freeholders, which is not so favourable to improvements as if they

were of greater extent, and held on lease under liberal

conditions.

The small figures on the back, the real family, and the next best

love which are but jet black, shining, and smooth appearance of the skin in

the fetlocks gives them. The agricultural labourers

are well off in general in the East Riding; they often

and with the farmers, and are at work early and late.

If the following are the fair and market days in the

West Riding of England:

Alberfeld, last Wednesday in April, last Wednesday
in May, last Wednesday in October, Wednesday after
St. Luke's, October 18; Adwalton, January 26, February
25, last Wednesday in Easter fortnight; Bishop Auckland,
last Thursday after Easter, Whitar-Thursday, and every
Thursday after Michaelmas for horses, cattle, etc.;

Boroughbridge, April 27, July 22, October 23 (horses
and cattle); Barnsley, last Wednesday in February pre-

ceding 28th, if 28th is a Wednesday then the Wednesday
before May 12, October 10; Bawtry, Holy Thursday,
Old Martin's, November 22; Bingley, January 25, August
25, 26, 27; Bradford, March 14, 15, June 28, 29, 30, cattle,
December 23, 24, 25, 26; Bentham, June 24, cattle; Boll
Clapham, St. Matthew, September 21; Doncaster, April
5, August 5, November 26, Monday before Old Candles-

day; Dewsbury, Wednesday before May 12, Wednesday
before October 10; Gargrave, Easter Monday, 10th;
Halifax, June 24; Holmfirth, May 24; Ingleston, November 17;
Keighley, May 8, November 8; Kirkby Stephen; Wharfedale, Wednesday after

Macadam, August 12, Monday after October 10, December
13; Lee or Legarn, August 24, September 17; Legh
July 10, November 8; Oulton, August 1, November
Penistone, Thursday before February 26, March
Tuesday before Old May 49, Thursday
Michaelmas-day; Pontefract, first Saturday
in December, Poodle-2, after that; Halifax,

Vol. XXVII.
Saturday after February 13, first Saturday after September 12, Saturdays before Palm-Sunday, Low-Sunday, and Trinity-Sunday, show of horses, February 5; Ripley, August 25, 26, 27, Thursday after January 24, Thursday after March 21; Ripley, Sunday after Easter-Tuesday, June 22, first Thursday after August 22, November 22; Rotherham, Whit-Monday, December 1; Sedbergh, March 20, October 20; Selby, Easter-Tuesday, June 22, October 10; Settle, Tuesday before Palm-Sunday, Thursday after the Good-Friday, Whit-Sunday, April 26, August 18 to 21, first Tuesday after October 27; Sheffield, Tuesday after Trinity-Sunday, November 28; Skipton, October 6; Slaidburn, February 14, 15, August 1, October 20; Smith, last Friday in April; Thornthwaite, Thursday after the Good-Friday, Tuesday after July 11, same days after October 11; Topcliffe, July 17, 18; Wakefield, July 4 and 5, November 11 and 12 (if on Saturday, Saturday before); Wetherby, Holy Thursday, August 5, November 22; Whitgift, July 12.

Divisions. Yorkshire.—Yorkshire is divided into the East Riding, North Riding, and West Riding. The East Riding is divided into the wapentakes of Buckrose, Dickerose, Harth, Holderness, Howdenshire, and Ouse and Derwen. The North Riding is divided into the wapentakes of Allertonshire, Bridlington, East Riding, Gilling, West Gilling, Hallifield, East West, West Riding, Pickering, Lythe, Ryedale, and the liberties of Langbaurgh and Whitby Strand. The West Riding is divided into the wapentakes of Askrigg, Barkston, Bilsdale, Bridlington, Skyrack, Staithleif and Everwoss, Staincross, Strafford and Tickhill, and the liberty of Ripon. The liberty of St. Peter of York (which comprises 51 places or parts of places in the East Riding, 42 in the North Riding, and 40 in the West Riding) is the liberty of the city of York. The wapentake of Askrigg, Barkston, Bilsdale, Bridlington, Skyrack, Staithleif and Everwoss, Staincross, Strafford and Tickhill, and the liberty of Ripon. The liberty of St. Peter of York (which comprises 51 places or parts of places in the East Riding, 42 in the North Riding, and 40 in the West Riding) is the liberty of the city of York. The wapentake of Askrigg, Barkston, Bilsdale, Bridlington, Skyrack, Staithleif and Everwoss, Staincross, Strafford and Tickhill, and the liberty of Ripon. The liberty of St. Peter of York (which comprises 51 places or parts of places in the East Riding, 42 in the North Riding, and 40 in the West Riding) is the liberty of the city of York. The wapentake of Askrigg, Barkston, Bilsdale, Bridlington, Skyrack, Staithleif and Everwoss, Staincross, Strafford and Tickhill, and the liberty of Ripon.
of it in the gardens of Bedale Hall, a mansion in the neighbouring

The tower of the church, which is very strong, was formerly used for defence by the inhabitants. The population of the township of Bedale was 1269 in 1831, and 1250 in 1841, but the whole parish contained, at those dates respectively, 2707 and 2603 inhabitants. The petty sessions for the division of East Anglia are held at Bedale.

The South, so called to distinguish it from the parish and village of North Cave, which lies a little to the north of it, is a parish and small market-town, partly in the liberty of St. Peter of York, and partly in the Hunley-Beacon division of the wapentake of Harthill, in the East Riding of Yorkshire, six miles west of Great Driffield and about three miles north of the Humber, near the western foot of the Wolds. The parish is extensive, and comprises the townships of South Cave, Broomfleet, and Great Driffield, the latter with a population of 2699 in 1831, and 3233 in 1841, including 69 inmates of the Workhouse, a number of almshouses, and seven monuments, supposed to be the monuments of Danish chieftains who fell in some engagement near the town, but nothing authentic is known concerning them. They are popularly called the ’Danes Graves.’ The chapelry of Little Driffield lies west of Great Driffield, and has a parish church, a chancel, and a modern vestry, all contributed to by the Earl of Harewood. The church is dedicated to the Holy Cross; it has no living, and is a perpetual curacy annexed to the latter. The church, dedicated to St. Peter, was rebuilt in 1807; and there is a Wesleyan chapel. The population of the township of Great Driffield on Sunday, was 92 in the former and 154 in the latter year; and that of the whole parish 2834 and 3477 at the same periods. Great Driffield is a polling-place for the Riding.

Easingwold is a market-town and parish in the wapentake of Bulmer, in the North Riding, about 208 miles from London, 13 miles north by west of York, and 11 miles east by north of Boroughbridge. The parish comprises the parishes of Brompton, Easingwold, and Easington, and is in the archdeaconry of Cleveland and diocese of York, with a gross income of 250l., in the patronage of the bishop of Chester. Easingwold contains places of worship for Roman Catholics, Independents, and Primitive and Wesleyan Methodists, and the former of these stands on an eminence above the town, and commands an extensive view over the antient forest of Galtres and the vale of Mowbray. There are several daily schools, two of which are endowed; a workhouse for the Easingwold Union, with an annual income of 230l.; and a very considerable church bank. It is a place of little importance, and the surrounding districts are not very fertile, but considerable quantities of bacon and butter are sent to York, and forwarded thence to London and elsewhere. The market is held on Tuesdays and Fridays, and there are fairs on the 22nd and 26th of September. Some chalybeate springs rise in the neighbourhood, one of which supplies a small bathing-house. The want of water-communication has been a disadvantage to this town, but 55 miles of railway are supplied by the Great North of England Railway, which runs near it. The population of the township was 1822 in 1831, and 2171 in 1841, including 67 persons in the Union workhouse; that of the whole parish, in the same years, 3090 and 2719 respectively.

Egton is a small market-town and parish in the east division of Langbaurgh Liberty, in the North Riding, about 7 miles west by south of Whitby, on the edge of the Egton Moors. The church, which is dedicated to St. James, is a partly Collegiate church, built in the 14th century, and was consecrated by the Bishop of Durham, in the 15th century, after the civil war between Charles I. and the parliament.

Driffield (Great), is a market-town and parish, situated partly in the liberty of St. Peter of York, but principally in the Binton-Beacon division of the wapentake of Hartill, in the East Riding of Yorkshire, 126 miles north by west of London. The town is pleasantly situated, at the foot of the Wolds, near one of the sources of the river Hull, about 193 miles from London, 26 miles east by north from York, 114 miles south-west of Bridlington, and 17 or 18 miles north by west of Hull. The parish, which contains a small portion of the township of Great Driffield the chapelry of Little Driffield, and the township of Emswell with Kellthorpe, is a discharged vicarage, in the diocese of York, with a gross income of 154l.; and the church, dedicated to All Saints, is an ancient structure, with a Norman tower, and consists of a nave, chancel, and a vestry, with a close of more than a mile on one side, street, with a clear trout-stream, which, below the town, is enlarged into a canal for communication with Hull by the river of the same name. It is lighted with gas, and there is a subscription library. The parish is a member of the Union, and contains a workhouse, a chapel, and a school. It has a market on Tuesday, and a fair on the 9th of August, and the 19th of September. Little Driffield was the burial-place of a celebrated Northumbrian king named Alchfrid or Alfred, who died here in 702; and it has been repeatedly stated that his remains were discovered entire, and re-interred, in 1784; but Baines says that this story is incorrect, the search made at that time being entirely fruitless. (History, Directory, and Gazetteer of the County of York, vol. iii., p. 194.) The neighbourhood also contains several monuments of archbishops who held in some engagement near the town, but nothing authentic is known concerning them. They are popularly called the ’Danes Graves.’ The chapelry of Little Driffield is a parish church, a chancel, and a modern vestry, all contributed to by the Earl of Harewood. The church is dedicated to the Holy Cross; it has no living, and is a perpetual curacy annexed to the former. The church, dedicated to St. Peter, was rebuilt in 1807; and there is a Wesleyan chapel. The population of the township of Great Driffield on Sunday, was 92 in the former and 154 in the latter year; and that of the whole parish 2834 and 3477 at the same periods. Great Driffield is a polling-place for the Riding.
York

The village contains Primitive and Wesleyan Methodist chapels, and several schools. The population of the parish, which is situated in the wapentake of Pickering, in the East Riding, was 975 in 1831, and 1101 in 1841.

Giggleswick, a handsome village, formerly a market-town, is in the West Riding, wapentake of Staincliffe and Eweppe, and township of Giggleswick, is less than a mile north-west from Settle, on the west bank of the river Ripble. The parish church is a large and handsome building, with accommodation for 1000 persons; the living is worth £212 per annum; and the value of an annuity of £60, reckoned upon the archdeaconry of Craven, and the new diocese of Ripon. Giggleswick has a grammar-school, founded by Edward VI., May 20, 1553, by letters patent. The present income is about 1150l. In 1833 there were 77 scholars, who were all educated gratuitously; scholars are admissible from all places. There are three masters, two for the classics and one for mathematics. There are six scholarships at Christ Church, Cambridge, for students from this school. Archdeacon Paley was educated here under his father, who was head master for nearly thirty years. About a mile north-west from the village is a curious cobbled and flowing well. It is sometimes quite dry, and has been observed to rise about twenty inches in five minutes. The flux and reflux is very irregular, and the cause of the phenomenon is unknown. The waters have been conjectured to arise from a small double siphon. The water is clear, cold, and wholesome.

Gibburn, a small market-town in the West Riding, in the wapentake of Staincliffe and Eweppe, and parish of Gibburn, is 22 miles north-east from the coast, and 25 miles south from the town of York. Gibburn is situated near the east bank of the river Ripble. The market is almost if not quite discontinued. There is no trade carried on. The church is supposed to have been built in the reign of Henry VII. The living is a vicarage in the gift of the crown, and of the net annual value of 101l. The population, in 1831, was 607; in 1841 it was 543.

Goole, a township in the parish of Southwark, in the West Riding, wapentake of Osgoldcross, on the western bank of the river, is situated near the junction of the canal for the Don made by Vermuyden, and 10 miles above the junction of the Ouse with the Trent. The township comprises 3020 acres, and in 1821 contained 71 inhabited houses and 450 persons; 226 houses and 1771 persons in 1841; and 388 houses and 2855 persons in 1841, including 390 in barges and other vessels. This rapid increase is to be attributed in the first place to the opening of the canal from Goole to Ferrybridge, by which the valley of the Lea, Halifax, Wakefield, and other parts of the West Riding and of Lancashire are accessible to Goole for shipment; and next, to the establishment of Goole as a binding-port in 1828. Small steam-boats ply on the canal from Goole to Ferrybridge. Vessels arrive from the ports of the Channel, and from the houses, and the Manchester in particular.

With these advantages and its favourable position, Goole promises in time to become a port of considerable importance. It is perfectly safe for vessels drawing from 15 to 17 feet water. The ship-dock is 600 feet long and 20 feet wide, with 16 feet depth of water, and will contain 200 vessels averaging 50 or 60 tons each. The basin or enclosure, which is 250 yards long by 200 wide, with 9 feet depth of water. The custom-house is a neat building. There are warehouses for the binding of goods and merchandise of every description; the wharves for the loading of foreign grain contains 5000 superficial yards of flooring; and there are thirty hands for the reception of timber under bond capable of receiving upwards of 300 loads; besides an extensive range of cellars. The gross duties received at the custom-house in 1842 amounted to £3935 12s. 3d. Export of coal coastwise in 1842 was 158,000 tons; a considerable part of the coal shipped is brought to London. The number of vessels from Goole arriving in the port of London has greatly increased within the last two years. The vessels belonging to Goole, according to the returns of 1842 were 203 and 178 above 50 tons, of the total burthen of 8717 tons; and 178 above 50 tons, of the total burthen of 15,610 tons; besides four steamers, averaging rather more than 50 tons. In 1841 the number of vessels which sailed coastwise from the port was 2553, total 157,719 tons; and there entered the port 3527 vessels, total 191,000 tons. In the same year 33 British, 214 Danish, and 4682 Danish vessels went to Goole from foreign ports; and 38 British and 16 tons, total 4671 tons, sailed for foreign parts. Only two of the vessels entered from or sailed for the colonies. The independent Wesleyans have places of worship. In 1821 the erection of a new church was commenced. In 1823 there were eight daily schools, one of which enjoyed an endowment of 20l. a year.

Guiseborough, Gisborough, or Guisborough, a market and a parish town, is in the West Riding, wapentake of Cleveland, and diocese of York, in the diocesan gross income of 72l.: the church, dedicated to St. Nicholas, was partly rebuilt in 1791. There are also two independent chapels, and places of worship for the Wesleyan Methodists and the Society of Friends. The town contains chiefly of one spacious street, leading east and west, with many good houses; a market-place, erected in 1821, on which is the town-hall, where petty sessions are held twice a week; a free grammar-school, founded in 1651 by the Rev. Robert Fargnoble, and called Jesus School, stands near the market-place. For the education of children, the schools which were established by subscription in 1790, but remodelled in 1821, when school-rooms were built for the education of 100 boys and 100 girls at a nation expense, are well attended. A branch of the Darlington Joint-Stock Bank; and a warehouse for the Guisborough Union, which comprises twenty-seven parishes. The market, which is well attended, is held on Tuesday; and there are several fairs and annual market. Most of the persons engaged in the sale of wool. At Guisborough the first alm-wares in this country were established, during the reign of Elizabeth. These works, which were funded by Sir Thomas Chaloner, have long been discontinued, but the manufacture has been transferred to Whitby.

Harrowgate, in the West Riding and wapentake of Wensleydale, consists of two adjoining villages, High Harrowgate, in the parish of Knaresborough, and Low Harrowgate, in the parish of Panell. The distance from London is 118 miles, 23 miles north-east from Knaresborough, and 20 miles west from York. Harrowgate has become populous within the last century in consequence of the rapidity of its medicinal springs, and is now one of the principal watering-places of the north of England. In 1831, 1715 persons, including 35 in the Union workhouse, and also the work-shops of Dale Common, Hutton Licros, Pinchinghams and Fockeets, making the total population 2210 in 1831 and 2015 in 1841.

Harrogate, in the West Riding and wapentake of Wensleydale, consists of two adjoining villages, High Harrowgate, in the parish of Knaresborough, and Low Harrowgate, in the parish of Panell. The distance from London is 118 miles, 23 miles north-east from Knaresborough, and 20 miles west from York. Harrowgate has become populous within the last century in consequence of the rapidity of its medicinal springs, and is now one of the principal watering-places of the north of England. In 1831, 1715 persons, including 35 in the Union workhouse, and also the work-shops of Dale Common, Hutton Licros, Pinchinghams and Fockeets, making the total population 2210 in 1831 and 2015 in 1841.
The population of High Harrogate, in 1841, was 3372, including 72 persons in Harrogate workhouse; the population in Low Harrogate, including the hamlet of Beckwith and 60 persons in the Harrogate Bath Hospital, was 1413; total 4785.

The mineral springs are of different qualities, sulphurous, chloride, and saline-sulphate. The sulphur well is in Low Harrogate, and is at all times sufficiently abundant. It is only for those on the spot, but to supply the demand for mineral water in the wapentake of Askrigg, Crescent Well, in Low Harrogate, is also a sulphur spring, but of somewhat weaker quality than the sulphur well.

The Cheltenham Water, as it is called, is a saline-sulphate spring. The Old Spa, the Tewit Well, and the New Chloride Well, are all chloride springs at High Harrogate.

Hawes, a market-town and chapel in the parish of Askrigg, wapentake of Hang West, liberty of Richmondshire, and in the Riding of North Riding, is situated on the south bank of the river Ure, at the head of Wensleydale, about 246 miles from London, 50 miles north-west by west of York, and 6 miles west of Askrigg. The houses are generally built of stone, which gives the town a very neat appearance. It is a market-town and chapel, and has a market on Tuesdays and the 28th of September. The neighbouring high lands supply coal and lime, and contain leaf-mines, which are worked, but are not very productive. A chapel of ease in the wapentake of Holderness and liberties of Hedon and St. Peter's, in the East Riding, about 179 miles from London, 5 or 6 miles east of Hull, in the promontory of Holderness. It is a very short distance from the Humber, with which it is connected. The town has a market on Thursdays, and was once a port of considerable importance, it has declined with the growth of Hull, and is now chiefly dependent upon the agriculture of the fertile and highly cultivated district which it is surrounded. A charter was granted to the town by the Crown in 1200, and it subsequently received several others down to the first year of James II. The income of the borough, in 1834, was £5733 5s. 6d., and at that time, although a borough court of sessions was no longer sitting, and the criminal jurisdiction had fallen into disuse, and the monthly adjournment of the quarter-sessions served the purpose of petty sessions. A court for the recovery of small debts is held here for the wapentake of Holderness. The borough sent members to parliament in the 23rd of Edward I., but subsequently ceased to do so until the accession of Edward VI., from which time it continued to return two members until disfranchised by the Reform Act.

The town contains several places of worship, and is a spa town, with a market-place in the centre, and a small town-hall. The Holderness Agricultural Society hold their meetings here, and have a valuable library. The ordinary market is held on Saturdays and Wednesdays at 7 a.m. and is attended by many persons for cattle, and sheep have been held on alternate Mondays between Sproxton and Midsummer; in addition to which there are several considerable fairs. The old creek having been choked up, an artificial canal, suitable for small boats, was formed from near Horden to the Humber, under an Act of 1774; and this has been very useful to the town, which had a population of 1850 in 1831, and 509 in 1841. Newton, near this town, was formerly a small hospital for lepers, founded in the reign of King John, the revenue of which at the dissolution was £15 15s. 10d.

Helmley, or Helmley Black-Moor, a market-town and parish of Bilsdale, in the wapentake of Holderness, is about 218 miles from London, 22 miles north of York, and 6 miles west by south of Kirkby Moorside. It is situated upon a gentle eminence sloping towards the river Rye, and appears to have derived its name from having been a place noted for its saline springs, for there are here a large number of jets, which are known to have fallen into disuse, and have not been restored. The market contains a chapel, a market-place, and is a spa town; the market-day is Monday, but the market has long since almost entirely ceased.
there are two annual fairs; and annual races are held in the neighbourhood. The town has a fine chalybeate spring, and good accommodation for sea-bathing, and is chiefly worthy of notice as a place of considerable resort during the season. In the immediate neighbourhood is the lake called Horse-meere, which covers about 430 acres, contains some picturesque islands, and affords an abundant supply of fine fish. The population of the parish, which is called Horsemere-with-Burton, was 780 in 1831, and 1065 in 1841.

Racecourse, market-town and parish in the wapentake and liberty of Howdenshire, in the East Riding, about 175 miles from London, 30 miles south-east from York, near the north bank of the Ouse, and south of the Hull and Selby Railway. The parish is partly extensive, and partly prismatic; contains 6500 acres of Howden, Asselby, Balkholme, Belby, Cotness, Kilpin, Kniellington, Metham, Skelton, Thorpe, Yorkfleet, and the chapelties of Barmby-on-the-Mash and Lexton, having an aggregate population of 4531 in 1851, and 5508 in 1841; the town is tolerably well-built. The parish church, which was rebuilt in 1805, is spacious and handsome, with an octagon tower containing eight fine-toned bells and a clock of bronze workmanship by Paine, of Westfield; the church has a powerful organ. The lord of the manor is the Duke of the house of Devonshire, and the rector is the Rev. Richard B. Hanson, descendant of the Keighley Union workhouse in 1841 contained 6 persons. The population of the town of Keighley in 1831 was 2925; in the population in 1841 was 13,738; in 1851 it was 11,176.

Keighley, a market-town, and parish, in the wapentake of Keighley, in the West Riding, in the wapentake of Stainleth and Exonume, and parish of Keighley, 206 miles north-north-west from London, and 38 miles south by east from York. The town stands in a deep valley, at the junction of two east streams which fall into the river Aire about three-quarters of a mile to the north-east, and about a quarter of a mile farther to the north-east is the Leeds and Liverpool Canal. The houses are well built, in some places tolerably well-built. The parish church, which was rebuilt in 1815, is spacious and handsome, with an octagon tower containing eight fine-toned bells and a clock of bronze workmanship by Paine, of Westfield; the church has a powerful organ. The lord of the manor is the Duke of the house of Devonshire, and the rector is the Rev. Richard B. Hanson, descendant of the Keighley Union workhouse in 1841 contained 6 persons. The population of the town of Keighley in 1831 was 2925; in the population in 1841 was 13,738; in 1851 it was 11,176.

Kirby-Moorside, or Kirby-Moorside, is a market-town in the wapentake of Ryedale, in the East Riding, about 224 miles from London, 23 miles north-east from York, 6 miles east by north of Helmsley, and 5 miles west by north of Pickering. It is a small and regular market-town, supposed to have been situated in the antient market-place, and was surrounded by deep hills. The parish is extensive, comprising the townships of Kirby-Moorside, Brandale and mixed with Green, with an aggregate population of 2244 in 1851, and 2258 in 1841. The town is a living of vicarage, and with the curacies of Cockan and Gillimoor, in the archdeaconry of Ouse, and diocese of York, with a gross income of £61. In this church there are three branches. The branch belongs to the Wesleyans, and Society of Friends. The town has three day and Sunday schools, and three branch banks; the town has a market on Wednesday and on Whit-Sunday and on Whitsunday, and the town has a weekly fair in the market-place, and in the market much salt and some linen goods made. The manor formerly belonged to the Earl of Westmoreland, who forfeited it to the crown in the reign of Elizabeth. The Duke of Buckingham, the Earl of Burlington, and the Duke of Bolsover, sit in the county court of the manor. The manor is held by lease and in the town much salt and some linen goods made. The manor formerly belonged to the Earl of Westmoreland, who forfeited it to the crown in the reign of Elizabeth. The Duke of Buckingham, the Earl of Burlington, and the Duke of Bolsover, sit in the county court of the manor. The manor is held by lease and in the town much salt and some linen goods made. The manor formerly belonged to the Earl of Westmoreland, who forfeited it to the crown in the reign of Elizabeth. The Duke of Buckingham, the Earl of Burlington, and the Duke of Bolsover, sit in the county court of the manor. The manor is held by lease and in the town much salt and some linen goods made. The manor formerly belonged to the Earl of Westmoreland, who forfeited it to the crown in the reign of Elizabeth. The Duke of Buckingham, the Earl of Burlington, and the Duke of Bolsover, sit in the county court of the manor.
of the net annual value of 393l. There is also a chapel belonging to the established church which has sittings for 200. The Methodists, Independents, and Roman Catholies had a chapel of worship, with sittings for about 800.  

In 1833 there were 16 days schools in Knarborough, one of which, containing 30 scholars of both sexes, was supported by endowment. There were also 3 day and boarding schools, 1 day and Sunday national school, and 8 evening schools, one of which was supported by the established church.

The chief manufacture is linen, which has long been established at Knarborough, and a large capital is invested in mills, machinery, and warehouses. The River Nidd flows through the transepted church, and considerable use is made at present, and which might be applied to a much greater extent if the increase of trade should require it.

Knarborough has returned two members to parliament since May, 1855. The right of election was originally in 84 burgage tenements, which were nearly all purchased by the earl of Burlington, and the duke of Devonshire was the possessor of them at the time of the Reform Act, under which Knarborough still returns two members. The parliamentary borough comprises the township of Knarborough and part of the township of Scriven-cum-Tenterdale.  
The population of the borough in 1841 was 5382. The number of electors on the register in 1835-6 was 262; and the number was 240, of whom 236 were 10l. householders.

The population of the town of Knarborough in 1821 was 5283; in 1831 it was 5290; in 1841 it was 4678 (2282 males, and 2440 females), including 57 persons in Knarborough and the adjoining places, and 12134 inhabitants.

About half a mile down the river are the ruins of a priory for friars of the order of the Holy Trinity, which was founded by Richard Plantagenet, brother of Henry III. There are some curious dwellings excavated in the rock, and near St. Robert's Church, which is said to have been formed in the thirteenth century by a hermit, son of the mayor of York, and St. Robert's Cave, which is supposed to have been his residence. This cave has been made notorious by the singular circumstances of the murder committed in it by a number of persons, till 1776.

On the north-west bank of the river, opposite the ruins of the castle, is a curious petrifying spring, called the Dopping Well. According to tradition Mother Shipton was born near this well. An extraordinary native of Knarborough, John Metcalfe, called Blind Jack of Knarborough, died there in 1810, at the age of 93. He lost his sight at the age of four years, and in different parts of his life acquired a reputation as a musician, a carrier, a guide, and a clog-dancer.

There are some medicinal springs in the neighbourhood of Knarborough, which were once much resorted to, but they have since been almost deserted for those of Harrogate and Scarborough.

Knyveton, town of Leyburn-Lounds, is a small market-town in the parish of Wensley, wapentake of Hang West, liberty of Richmondshire, and the North Riding of the county, about 220 miles from London, 36 miles north-west from York, 3 miles north of Middleham, and 8 miles south of Richmond. It consists chiefly of a spacious oblong square of well-built houses, in the centre of which a market is held every Friday, where a considerable quantity of corn is sold. It has also fairs on the second Friday in February, May, October, and December, when many cattle and 2400 sheep are sold. It is pleasantly situated in a picturesque scenery, and has places of worship for Independents, Wesleyan Methodists, and Roman Catholics, several schools, a branch bank, and a public library. The town contains one inn and three public houses, and has supply less than 1000 people.

In the neighbour of Leyburn are the remains of Bolton and Middleham castles, and of the abbey of Jervaux and Coverham, and the mansion and pleasure-grounds of Bolton Hall. The population of the township was 1003 in 1831, and 914 in 1841, including 26 persons in Leyburn Union workhouse.

Malton, New, is a parliamentary borough and market-town in the wapentake of Ryedale, in the North Riding, about 214 miles from London, 17 or 18 miles north-east of York, and 3 miles north of the town of Scarborough. It is situated on the north bank of the river Derwent, over which is a stone bridge to connect it with the suburb of Norton, and which here forms the boundary between the North and East Ridings. The borough comprises and is co-extensive with the parishes of St. Leonard and St. Michael, but for parliamentary purposes it unites with the adjoining parish of Old Malton, and is returned by the vote of two members. Both of the parishes of New Malton, with that of Old Malton, form a perpetual curacy, in the archdeaconry of Cleveland and diocese of York, with a gross income of £150. The parson of St. Michael is supposed to have been originally chapels to Old Malton, which is presumed to have been the mother parish and church; and the former has a tall spire, the upper part of which has been left unfinished, in the form of a tower. According to the popular story, its weight should prove too great for the edifice. The town also contains places of worship for Roman Catholics, Presbyterians, Independents, Baptists, Primitive Methodists, members of the Society of Friends, and Unitarians; for schools, there is a grammar school, a national school, a spacious workhouse for the Malton Poor-Law Union, which comprehends 68 parishes; a large marketplace, including a town-hall; a neat theatre, built in 1814; and a handsome suite of public rooms, in connection with which are a newspaper and a subscription library. There were formerly two market-crosses, both of which are destroyed. The town is generally well built, and is favourably situated on an eminence; and it has a brisk trade, of which it is greatly aided by its being well supplied with trade, having been made navigable to Malton, under an Act of the reign of Queen Anne, and more recently to a higher point. The principal articles of trade are corn, bacon, butter, and other agricultural produce, which are sent to several of the markets in the district. The town has a market-place, where New Malton, and 4021 in 1841; that of Old Malton, at the same dates, 1204 and 1206 respectively.

Old Malton stands about a mile north-east of New Malton, on the same side of the river, and it has a very antient church, dedicated to St. Peter, which, with the vicarage, remains of a priory, founded in 1150, for Gilbertine canons, the revenues of which amounted, at the dissolution, to 275l. 7s. It has a free grammar-school was founded here in 1547, by Robert Holgate, archbishop of York, with an endowment which now produces about 100l. per annum. The town contains a Wesleyan chapel and some daily schools. It is observed in the Report of the Boundary Commissioners, that the presumption of some closer connection than that of mere vico age existing, between New Malton and Old Malton, both by the Report of a Committee of the House of Commons in 1659, deciding that Old Malton had a joint right with New Malton in the election of members of parliament, and by the return of two members, the inhabitants of New Malton, over whose commons and wastes belonging to Old Malton. The town is fortified with its lime-quarries.
tract of impassable marsh between the river Derwent and the Wolds. Numerous Roman coins, urns, and the remains of a cairn have been found here. In the Saxen times Malton became a royal villa to King Edwin; and after the Normans conquest the baronial family of Vesey, or De Vesey, built the old Wapentake of Richmond west as the property mentioned above. This castle was demolished by Henry II., but while it stood the town was burnt down by Archbishop Thurstan, who besieged it for the purpose of dislodging a party of Scots who had obtained possession and garrisoned the town. The old town was rebuilt on the site of St. Mary's, and the church was dedicated to Our Lady of the same name and was the church of St. Mary the Virgin. The wapentake of Malton, with a large part of that name, was decided by St. Mary's, and then received the name of New Malton. A noble castellated mansion was erected on the site of the ancient castle, about the close of the sixteenth century, by Ralph, Lord Eure; but in 1674, as his grand-daughters could not agree concerning the property, the greater part of the mansion was pulled down by the sheriff, under an order of court, divided the materials between the contending parties, leaving only the lodge and gateway standing as a monument of their folly. About a quarter of an annum from New Malton is a mineral spring, said to be similar to those of Scarborough, and to be an efficacious chalybeate.

Masam is a parish and market-town, partly in the liberties of St. Peter's, York, and partly in Wapentake of Hang-East, in the North Riding, about 216 miles from London, 30 miles north-west of York, and 14 miles south by east of Richmond, pleasantly situated on the western bank of the Ure. In a very fertile country, nearly level, to the north of the West Riding. The parish comprises the manors of Marsham, Burton-unpon-Yore, Ellington, Ellington, Fearby, Healy-with-Sutton, Itton-with-Pott, and Swinton-with-Wathermark, and had an aggregate population of 2995 in 1831, and 2974 in 1841. The living is a perpetual curacy, valued at £36 per annum, from the benefaction of three other persons. The town is well built, and has a considerable manufacture of woollen yarn, and a flax-mill, which in 1838 employed 122 persons. Coarse straw-plait for making hats is also produced. The town has a weekly market, a little importance, on Wednesday, and fairs on the 17th, 18th, and 19th of September. The population of the township of Marsham alone was 1276 in 1841, and 1316 in 1841.

Middleborough, or Middleburgh, is a parish and township, is chiefly in the western division of Langbaurgh liberty, in the North Riding, situated on the southern shore of the Tees, close to its mouth, and which has risen to considerable importance in consequence of the formation of a branch or extension of the Stockton and Darlington Railway for shipping coals here, so as to avoid the river navigation. Middleborough lies about 5 miles east by north of Stockton, and formerly had a chapel dedicated to St. Hilda, which is now in ruins, but of which no remains are extant. It has been found here is some burying-ground. The parish of Middleborough contains the township of that name and the township of Linthorpe, and had a gross population of 236 in 1821, 383 in 1831, which is increased by the addition of the railway station, 575 in 1841, including 40 persons in barracks and tents, but exclusive of 109 persons absent from home, and 50 who had emigrated to America in that year. The township of Middleborough alone contained only 40 persons in 1821, 54 in 1831, and 66 in 1841, and the gross population was 5118 in 1831, and 2273 in 1841. The living is a vicarage, with the advowson of the Skell and Drighlington, formerly in the peculiar jurisdiction and patronage of the dean and chapter of Durham. The parish is peculiarly strongly connected with the Stockton and Darlington Railway, and the river Tees, which forms one side of the boundary of the electoral district. The parish comprises the borough and township of Middleborough, the township of Carnaby, the chapelry of the church of St. Peter's, and some foundries, a pottery, and other manufactures. The living is a perpetual curacy, in the archdeaconry of Cleveland and diocese of York, the gross income of which in 1831, was 337. The township contains Independent and Wesleyan Methodist chapels, and several schools.

Middleham is a parish and small market-town in the wapentake of Haug-West, liberty of Richmondshire, and North Riding of the county, about 226 miles from London, 41 miles north-west of York, and two or three miles west of Leyburn. The living is a perpetual curacy, with the vicarage of the Skell and Drighlington, formerly in the peculiar jurisdiction and patronage of the dean and chapter of Durham. The living is a vicarage, with the advowson of the Skell and Drighlington, formerly in the peculiar jurisdiction and patronage of the dean and chapter of Durham. The parish is peculiarly strongly connected with the Stockton and Darlington Railway, and the river Tees, which forms one side of the boundary of the electoral district. The parish comprises the borough and township of Middleborough, the township of Carnaby, the chapelry of the church of St. Peter's, and some foundries, a pottery, and other manufactures. The living is a perpetual curacy, in the archdeaconry of Cleveland and diocese of York, the gross income of which in 1831, was 337. The township contains Independent and Wesleyan Methodist chapels, and several schools.
and Wesleyan Methodists, and numerous daily and Sunday schools, three of the former of which are partially supported by endowments, and one, now the parochial school, was formerly a grammar-school, of royal foundation, though at what date is uncertain, and where several piles or portions were met. There was antiently a hospital dedicated to St. James, and founded by Hugh Pudsey, bishop of Durham, the clear revenue of which, at the time of the dissolution, was 56l. 2r. 2d, and of the site of which some indications yet exist near the town. The church house is several merlons, or White Friars, dedicated to St. Mary, and there is some land here in the reign of Edward III, for the purpose of building a house and church. The town now contains an hospital, or Maison Dieu, founded in 1476 by Sir Hugh Dalmer and Dr. John Lumby, who conveyed East Riding, and rebuilt by the inhabitants, but for a smaller number. Northallerton is lighter with gas, and has a handsome modern sessions-house, to which is attached a House of Correction. Not being a corporate town, it has no municipal police, but it is yet the residence of the Bishop of the county magistrates. It has a Court of Requests for the whole of the manor of Allerton and Allertonshire, comprising 32 townships; and the quarter-sessions for the North Riding are held here. It likewise contains the Reformatory School, founded by Bishop Nidd, appears to be in a state of rapid improvement.

According to Baines 'Religious State of the Manufacturing Districts,' 1843, there are in the township seven episcopal churches and a considerable number of dissenting societies, in all twenty-five places of public worship, with sittings for 5700 persons: there are four infant schools, 12 private schools, three factory schools, and seven public day-schools, in all twenty-six day-schools, bank schools, and schools supported by the established church, and fifteen supported by different classes of dissenters, in all eighteen Sunday-schools, with 1060 scholars. The present population, according to Baines, is 7996. There are several iron mines in the neighborhood, but the prosperity of the town seems to be chiefly derived.

Patrixton is a parish and market-town in the southern division of the wapentake of Holderness, in the East Riding, about 188 miles from London, 57 miles south-east of York, and 18 miles north-west of Holderness. It is a pleasant place for antiquities, and is supposed by some writers to be the Praetorian of the ancient geographers, an opinion somewhat strengthened by the discovery, about eighty years since, of part of a Roman altar. Other writers derive the name of the town from St. Patrick, a missionary consecrated by the bishop of York, in 440, and of the parish was 1288 in 1831, and 1402, including 72 inmates of the Union workhouse and 16 persons in barges, in 1841.

Penistone, a small market-town on the right bank of the Don, in the West Riding, wapentake of St. persons in barges, 18 miles from London, on the road from Sheffield to Huddersfield, 13 miles from each place. It is situated on the edge of the dreary moors which form the borders of York-

shire and Lancashire. The climate is cold, and the harvest is sometimes not gathered in before November. The parish comprises 21,509 acres, and consists of the chapelry of Denby, and the townships of Gunthwaite, Humbel, Ingibirthworth, Langsett, Oxapring, Penistone, and Thuerdgate. The population of the parish was 502 in 1821, 5201 in 1831, and 5907 in 1841. The church is dedicated to Penistone, and the townships of Denby, Gunthwaite, and Highburgh-worth: the living is a perpetual curacy, net value 147. The linen manufacture is carried on in the town, and there are 143 schools, and 1634 scholars; besides two or three tolerably large schools.

P. C. No. 1707.
York 998

sclars. The population of the township was 645 in 1821, 703 in 1831, and 738 in 1841. The population of Thurlstone in 1841 was 1872. The Sheffield and Manchester line, with a depot station in the town, and the Rotherham line, includes 225 persons who were employed on its construction. Dr. Sanderson, the blind mathematician, was a native of the parish.

Pickering is a parish and market-town in the wapentake of Pickering-Lytham, in the North Riding, about 226 miles from London, 26 miles north-east of York, and 18 miles west of Scarborough, pleasantly situated on a small eminence, at the foot of which runs the rivulet called Pickering Beck. The parish comprises the townships of Pickering, Kirkleatham, Mantishoe, and Newton, and the chapelry of Goathland or Goatland, and had an aggregate population of 3346 in 1831, and 3901 in 1841. The living is a discharged vicarage, with the curacy of Newton, a peculiar of the dean of York, with a gross income of £145. The town is connected with the meeting of Pickering by a main road described in a previous column, and is long and straggling; and it contains an antient and spacious church, with a lofty spire, dedicated to St. Peter; several dissenting places of worship, and several schools, one of which is endowed. Various other places of amusement, like the various lairs are situated and connected with the town. Pickering was 2555 in 1831, and in 1841, 2992, including 50 inmates of the Union workhouse and 11 persons in tenements.

Pickering is a parish and market-town, partly in the liberty of St. Peter of York, but chiefly in the Wilton-Beacon division of the wapentake of Harthill, in the East Riding, about 195 miles from London, 13 miles east by south from York, and 7 miles north-west of Market Weighton. The town is situated on the level country, two miles from the western edge of the Wolds, and is connected with the river Derwent by the Picklington Canal, which is described elsewhere. The parish contains the townships of Picklington, Meltonby, and Owathorpe, and the chapelry of Yapham, and had an aggregate population of 2255 in 1831, and 2562 in 1841. The living is a discharged vicarage, with the curacy of Yapham-cum-Meltonby, a peculiar of the dean of York, with an income of £137. The parish church, dedicated to All Saints, is a very remarkable building, containing several places of worship for Roman Catholics, Independents, and Primitive and Wesleyan Methodists; a well-endowed free grammar-school, founded in the 6th year of Henry VIII., by John Dowman, LL.D., with which are connected five exhibitions at St. John's College, Cambridge, which has an income exceeding 1000l. per annum; and among several other daily schools, a national school, liberally supported by subscriptions. The buildings of the grammar school were re-erected in 1819. Pickington is one of the polling-places for the township of Pickering, the centre of a Poor-Law Union comprising 47 parishes; it has three branch banks, and petty sessions for the Wilton-Beacon division are held here. It has a market on Saturday, and large sheep and cattle fairs are held on March 7 (or the nearest Monday), May 8, August 1, and November 9. At Barnsley Field, near the town, four human skeletons, with an urn bearing some antient characters, were discovered in 1763. The population of the township of Pickington was 3341 in 1831, and 3925 in 1841.

Reeth is a small market-town in that part of the parish of Grinton which belongs to the wapentake of Gilling-West, in the liberty of Richmondshire and the North Riding, about 230 miles from London, 46 miles north-west from York, and 10 miles west by south from Richmond, on the northern bank of the Swale, about half a mile above the junction of the Arkle. The town is irregularly built in a highly picturesque situation, and it contains independent and Wesleyan schools, a grammar-school, two national schools, one endowed in 1643, by Alderman Richardson, of York, and the other in 1814 and 1815, by the members of the Society of Friends, the schoolrooms of the latter being also used as a place of worship by persons of the founders' persuasion. The town has a very particular manufacture of knitted stockings, many of which are exported; and many of the inhabitants receive employment from lead-mines in the neighbourhood, the produce of which is of great purity, and is sought after for the manufacture of hats, and for the making of snuff. The lead mines produced a few years since about 5000 or 6000 tons of lead annually. There is a branch of the Swaledale and Westmoreland Banking Company in the town, which has a market on Friday, under a charter of the 8th year of Ktvem and Mary, and several fairs, the days of which are variously given by different authorities. Near the town are the remains of an entrenchment, called Maiden's Castle, about 100 yards square, and of some others, one of which is much larger; and from some remains which have been discovered here there is reason to believe that the town was once inhabited by the Romans. Near the town, in the hamlet of Healaugh, are the remains of a house said to have been inhabited by John of Gisburne, one of the robbers of the diocese of Chester, but now in the architecture of the diocese of York. The town was situated on the north side of the river Nidd. The town is antient, and contains some curious old monuments and remains of the Irton church, which was the site of the diocese of Chester, but now in the architecture of the diocese of York and diocese of Ripon, in the gift of the Ingilby family, and of the net annual value of £662. The chief distance of the place is the castle of the family of Ingilby, which is now a ruin, but had been once built. There is a grammar school, which in 1833 contained 40 male, which were built and endowed in 1702, by two young daughters of Sir William Ingilby. The population of the township in 1831 was 270; the population of the town is not given in the Population Returns for 1841.

Saddlesworth is a village in the West Riding, in the wapentake of Agbrigg and parish of Rochdale, 18 miles north-west from London and 54 miles south-west from the city of York. The town is situated in a fertile vale belonging to a district in which the woollen and cotton manufactures have advanced with amazing rapidity and to a very great extent. The district is 7 miles long and 3 miles wide, and includes about 100 manufactories, and has an aggregate population of 18,970. The population in 1811 was 12,579; in 1821 it was 13,982, in 1831 it was 15,986, in 1841 it was 16,829, at which time there were 553 houses unincorporated, owing to the depopulation state of the manufactures.

Sedgebergh is a small market-town in the West Riding, in the wapentake of Staintain and Ewcrross, 256 miles north-west from London, and 7 miles north-west from York. The town is situated in a sheltered and fertile vale among rugged mountains, and is the chief town of the parish of Sedgebergh, in the diocese of Chester, but now in the archdeaconry of Richmond and diocese of Ripon, in the gift of Trinity College, Cambridge, and of the net annual value of £664. The parishes are places of worship belonging to the Methodist Connexion and Independents. The daily schools at Sedgebergh, one of which is a grammar-school, and had 100 scholars. The school was founded by Dr. Roger Lipton, provost of Eton, in the reign of Edward VI. After some time the funds were misapplied, but restored 1618, and Norden, a fellow of King's College, Cambridge, and Sir Arthur Denny, who also rebuilt the school. The endowed amount to about 500l. a year, paid to the head master but out of which he pays 100l. a year to the second master besides other expenses. The head master is paid 100l. a year, and fellowships of £20 and £10 in the college, Cambridge, and two fellowships for poor students in the school. There are manufactures of cotton and silk. The town is not sufficient for the supply of the town is obtained from the mine about two miles distant. The population of 500
Selby, a market-town in the West Riding, in the wapentake of Staincliffe and Ewecros, and parish of Selby, 127 miles north-west from London, and 14 miles south by east from York; it is situated on the west bank of the river Ouse, which is navigable to Selby for vessels of about 200 tons burthen. An excellent timber bridge crosses the river, below the town. It was formerly a strong and well-built, paved, and lighted. The town-hall, a neat brick edifice, was built in 1823. There is a fine old Gothic market-cross. The church, dedicated to St. Mary and St. Germain, is part of an abbey of Benedictine monks, which was founded by William the Conqueror, and was in the possession of this family, and was a splendid establishment till the dissolution by Henry VIII. Henry I. was born at Selby in 1068. The church is a spacious structure, and contains some curious old monuments. The architecture is of different periods, some of it very beautiful; in 1819 it was 203 feet long. The tower fell down in 1800, and was rebuilt in its present form about 1763. The living is a perpetual curacy, in the gift of the Hon. E. R. Petre, with an average net income of £135. 2s. 8d., and is invested in the Westminster, Union, and other charities. Steam-packetts ply between Selby and Hull, and a canal from Selby joins the Aire and Calder navigation, and thus communicates with Leeds. There is also a railway between Selby and York, and Hull. Selby railway joins the Selby and Leeds railway a little to the west of Selby, and thus makes a railway communication between Leeds and Hull. There is a branch custom-house at Selby, by which vessels can proceed direct to the port of London.

In 1833 there were ten daily schools, of which one was a grammar-school with an endowment of 53l. 17s. 10d. a year, to which upwards of 60l. is added annually by donations and subscriptions. The population in 1841 was 5376, of whom 275 persons were washed in baphe and 89 in the Selby Union workhouse. In 1821 the population was 4097, and in 1831 it was 4000.

Skipton, a small market-town, in the West Riding, in the wapentake of Barkston-Ash and parish of Sherburn, is 133 miles north by west from London, and 16 miles south-east from York. The town is situated on a small river, and is a market and manufacturing town. There are seven daily schools. The Commissary of Education at York formerly had here; it is a spacious structure, and the house is described as exhibiting a peculiar and magnificent system of architecture. The living is a vicarage, in the patronage of John Smith, of Staincliffe, Esq. The value of the entire gross soil is £15 a year. The population in 1841 was 5900; 8350 in 1831, and 10,444 in 1841. There is a market and a grain market, and also a fair by the annual value of £750. The Wesleyan Methodists have a chapel here, with a Sunday-school attached, which in 1833 was attended by 171 children. There is a national school, partly supported by a small endowment, the date of which is unknown; also almshouses for six poor persons founded by the Yorke family, and others for six widows, rebuilt in 1802 by Lord Downes, who has a seat in the parish. The parish of Smith is very extensive, and extends into the wapentake of Barkston-Ash. It comprises the chapelry of Arnside (a perpetual curacy, net value 51l. 13s. 4d.), with that of Hook (a perpetual curacy, net value 56l.), population 1821; the chapter of Rawcliffe (a perpetual curacy, net value 120l.), population 1821; and the chapelry of Hook (a perpetual curacy, net value 56l.), population 1821; the chapter of Rawcliffe (a perpetual curacy, net value 120l.), population 1821; and the townships of Balne, Cowick, Goole, Gowdall, Hook, Hensall, Holmville, and others for six widows, rebuilt in 1802 by Lord Downes, who has a seat in the parish. The parish of Smith is very extensive, and extends into the wapentake of Barkston-Ash. It comprises the chapelry of Arnside (a perpetual curacy, net value 51l. 13s. 4d.), with that of Hook (a perpetual curacy, net value 56l.), population 1821; the chapter of Rawcliffe (a perpetual curacy, net value 120l.), population 1821; and the townships of Balne, Cowick, Goole, Gowdall, Hook, Hensall, Holmville, and others for six widows, rebuilt in 1802 by Lord Downes, who has a seat in the parish. The parish of Smith is very extensive, and extends into the wapentake of Barkston-Ash. It comprises the chapelry of Arnside (a perpetual curacy, net value 51l. 13s. 4d.), with that of Hook (a perpetual curacy, net value 56l.), population 1821; the chapter of Rawcliffe (a perpetual curacy, net value 120l.), population 1821; and the townships of Balne, Cowick, Goole, Gowdall, Hook, Hensall, Holmville, and others for six widows, rebuilt in 1802 by Lord Downes, who has a seat in the parish. The parish of Smith is very extensive, and extends into the wapentake of Barkston-Ash. It comprises the chapelry of Arnside (a perpetual curacy, net value 51l. 13s. 4d.), with that of Hook (a perpetual curacy, net value 56l.), population 1821; the chapter of Rawcliffe (a perpetual curacy, net value 120l.), population 1821; and the townships of Balne, Cowick, Goole, Gowdall, Hook, Hensall, Holmville, and others for six widows, rebuilt in 1802 by Lord Downes, who has a seat in the parish.
six miles, the Cleveland hills, including the mountain called Roseberry Topping, rise in the form of a semicircular amphitheatre, of which Stokesley is the centre. The parish comprises the townships of Stokesley, Great and Little Busby, Easby, and Newby, and had an aggregate population of 2376 in 1831, and 2734 in 1841, including the non-residents mentioned below. The living is a rectory

of the deanery of Cleveland and diocese of York, and in the patronage of the archbishop of York, with a gross income of 13252.

The parish church, there are places of worship for Independents and Primitive and Wesleyan Methodists. Among Garnish schools are national schools for both sexes, partly supported by endowment. The town consists chiefly of one street, with many well-built houses, and it has an annual court-leet and weekly petty sessions. It has a considerable manufacture of linens, a good market on Saturday, and a fair on the Saturday before Easter Sunday, Trinity Sunday, and Old Lammas-day. Stokesley is a polling-place for the North Riding, and the township had a population of 1967 in 1831, and 2310 in 1841, including the hamlet of Tanton, 16 persons in the Union workhouse, 24 in farms, and 270 visitors on the annual fair.

Tadcaster, a market-town in the West Riding, partly in the wapentake of Barkstone-Ash and partly in the Ainsty of York, 155 miles north-north-west from London, and 9 miles south-west from York. It is situated on both banks of the Wharfe, over which it is a handsome stone bridge constructed with stones taken from the ruins of a castle which formerly stood on the south side of the river. The river is navigable for boats. The town has little trade, but it has previous to the formation of the wapentake between York and Leeds and Manchester, a place of great thoroughfare from York to the south-west. The church is dedicated to St. Mary; the living is a vicarage, in the archdeaconry and diocese of York, in the gift of the dean and chapter of York, and the net value of 224 has.

In 1833 there were seven daily schools, one of which was a grammar-school endowed with the rent of a farm, for which twenty scholars were free, and ten others were paid for by their parents. Another daily school was endowed by, and is supported for forty years, but it contained only twenty-four when visited by the Education Commissioners in 1833. There were also two day and boarding schools, and three Sunday-schools. The population in 1841 was 1825; in 1831 it was 1600. Tadcaster is the Calcaria of the Romans, which was an outpost of their chief military station Eboracum, now York.

Thirsk is a parish, market-town, and parliamentary borough, situated partly in the liberty of St. Peter of York, but chiefly in the wapentake of Bifordthorpe, in the North Riding, 14 miles south-west from York, 14 miles north-west of York, and 10 miles south-south-east of Northallerton. The parish comprises the borough of Thirsk, the township of Castle-Isebeck and Miniot, and the chapelry of Sowerby, and had an aggregate population of 2439 in 1841. The living is a vicarage, in the archdeaconry of Cleveland and diocese of York, with a gross income of 1437.

The church, which is dedicated to St. Mary Magdalene, is a large and handsome Gothic building, supposed to have been turned out of the ruins of the ancient castle. Thirsk contains likewise places of worship for the Society of Friends, Independents, and Wesleyan Methodists. One of the schools of the town is conducted in a school-house under the chancel of the church; another is a school for educating poor girls.

The town is pleasantly situated on both sides of the stream called Codebeck, a feeder of the Swale, in the fertile vale of Mowbray; that portion which lies east of the beck being called Old Thirsk, and that on the west side New Thirsk. As the town is in the extreme south-western extremity of the town is the site of the castle, which is said to have been erected by the Mowbray family in the year 959, and to have been a noble pile of building, but scarcely any vestiges of it now remain except the mount on which the keep formerly stood.

Old Thirsk consists of a long range of cottages on the road to Yarm and Stockton, and of a square, called St. James's Green, surrounded by buildings of a similar character, which marks the site of an ancient chapel founded by William de Mowbray, in the time of Henry I. Upon another green at Old Thirsk formerly stood a venerable elm-tree, under which, from time immemorial, the election of members of parliament took place, and where also it is said that Henry Percy, the fourth earl of Northumberland, was put to death during a popular tumult in 1482. The present manor house was destroyed by fire in 1818, having been inhabited by several mischievous boys. A substantial stone bridge, with arches of sufficient size to allow the free passage of the Coquet and the Swale, lies near the ruins and the mending of which connects the old with the new town, is a very useful and extensive market-place.

The present church is on the north-east extremity of the new town, and it is supposed that there was formerly a church in the old town, of which vestiges remain. It is a large and handsome building, though coarse linens and saddlery are made at the town; but it has a well-supplied market on Monday, where great quantities of provisions are bought for the market and other places; and there are fairs on Shrove-Tuesday the week before Easter, and on October 28 and 29, and the first Tuesday after December 11. The Great North of England Railway also passes a little west of the town, which is not a corporate borough but a burgage tenure borough by prescription. Old Thirsk town was called Thornede Waterhouse, is on the south bank of the Tees, and here are ships, rope, and timber yards, and wholesale merchandise. The tide rises several feet, and boats cannot ascend the river for three days; but at neap-tides they do not come farther than the Newbridge, on the Dutch river, 4 miles from Thirsk, and is the east side of the town the Stainforth and Keels are 10 miles long, connects the Trent and the Don; and at Newbridge, 4 miles from Thirsk, is a market-town. The Dutchman, in the year 1601, and the former is of sufficient importance to have been selected as one of the places for returning the average prices under the Com Act of 1842. A great portion of the surrounding country was once a marsh, but it has been drained by the Dutch, who, for reasons of economy and agriculture, commenced in the reign of Charles I. Cornelius Vermuyden, a Dutchman, who came over as a number of his countrymen. (A Newhoelme.) The idea of this immigration is not yet extinct in the vicinity, and families still exist who trace their descent to Dutch settlers.

The waggon in common use is evidently Dutch, and is not found beyond a limited district. The priest of Thirsk comprises 10,840 acres; and the population in 1841 was 2635, of whom 2480 were 840 houses inhabited, 68 uninhabited, and 1 building in 1841, 706 inhabited, 123 uninhabited, and there were 600,000. The town is lighted with gas. The church was formerly a chapel of ease to the parish of Thirsk, but it is now a separate parish. In consequence, it is said, of a funeral party coming over the marsh (now drained) having narrowly escaped drowning by the upsetting of the boat. The living is a perpetual

vicarage, in the archdeaconry and diocese of York, with an annual value of 117. The Universalist Baptists have a chapel, which is licensed for the celebration of marriages; and the Methodists, Independents, and Quakers have also places of worship. In 1833 there were 32 children educated from Travis's charity, and in 1841 from Dr. Brook's charity, and Dr. Brook's monuments being 1705 and 1706. Thirsk is in the central

area of Poor-Law Union.
Tickhill, a small market and post town in the West Riding, in the wapentake of Strafforth and Tickhill, on the borders of Nottinghamshire, 157 miles from London, and 43 miles south from York. The substratum of the town is limestone, which gives the place a very clean appearance. The streets are disposed nearly in the form of a cross by the roads from Doncaster to Worksop, and from Rotherham to Batley. The town is neither paved nor lighted, and the market, which is simply for butter, eggs, &c., was once but twice a week, and was disused until revived a few years ago. The market-cross is about 30 feet in height, and is a fair in August for cattle and merchandise. Tickhill was a place of importance in the middle ages, as may be inferred from its giving a name to the wapentake. Camden says, "Tickhill was of dignity heretofore, that all the manors hereabouts were inherited by the Honour of Tickhill." The castle is said to have been erected by Roger de Bully, one of the Norman followers of William the Conqueror, but several times reverted to the cross of St. Peter of York, but chiefly in the Holme-Beacon division of the wapentake of Hurthill, in the East Riding, about 188 miles from London, 10 miles south-east from York, and 10 miles west by north of Catterick. The church of Tickhill contains one chancel and three aisles, and six daily schools. There is an almshouse, a memorial foundation, for 14 poor widows. The parish of Tickhill comprises an area of 6470 acres, and includes the parishes of Staincross and Wicker Humley, which contain 140 acres. The parish was assessed in 1831, 821, 2064 in 1831, and 2040 in 1841, including 19 in entails. The population of the township of Tickhill being 1841: and it is stated that 60 persons were absent. Market-day is Monday; and the nearest post towns are Doncaster, at one mile, and the liberty of St. Peter of York, at nearly 1 mile. The church, which is dedicated to St. Saints, is an ancient edifice, with a comparatively modern spire, which has been substituted for an old one of wood; and the town contains chapels for Independents, Wesleyans, and other dissenters, and grammar-school, for various other schools. There are also a well-attended market, at which much corn is sold, on Wednesday, and fairs are held on the 14th of May and the 25th of September. The population of the township was 2821 in 1831, and 1847 in 1841.

The town is well built, and pleasantly situated on the north bank of the river Wharfe, over which there is a handsome stone bridge with a set of four elegant arches, and a dam constructed, over which the river forms a pretty cascade. By means of the dam several mills are worked, which grind corn, press oil-seeds, and rasp logwood for dyers. The town is a chapel-of-ease to Spofforth, and the living is a perpetual curacy, in the archdeaconry of Craven and diocese of Ripon, in the gift of the rector of Spofforth, of the net annual value of 100L. The Wesleyan Methodists and Independents have places of worship. The population of the township in 1841 was 1439; in 1831 it was 1321.

Yarm or Yaurm, is a parish and market-town in the western division of the liberty of Langbaurgh, in the North Riding: the town occupies a low peninsula nearly surrounded by the river Tees, about 237 miles from London, and 44 miles north-north-west from York. The town appears to have fallen in importance with the rise of Stockton, which is about 4 miles to the north-east, on the south side of the river, and partly, perhaps, in consequence of the destructive floods to which its low situation subjects it. In 1753, and again in 1822, the water covered the town to the depth of 7 feet, and in 1771 it rose still higher, being considerable and destructive. The town contains some good houses. The Tees is here crossed by a bridge of five arches, built in 1400 by Walter Skirlaw, bishop of Durham, and since much improved; and in 1805 an elegant iron bridge, of one arch, 180 feet span, was opened for the convenience of the trade on both banks of the river. The town is well supplied with coal from the Wensleydale and Guisborough districts. The town is largely supplied by the exportation of agricultural produce, but the corn trade, though formerly considerable, has declined. The town also derives some benefit from the salmon fishery in the Tees. The weekly market is on Thursday, and there are two fairs, one on the Thursday in Ascension week, or the 2nd of August, and the 19th and 20th of October, that on the last-mentioned day being a great cheese-fair. A court for the recovery of small debts is held here twice in every year. The population of the parish was 1630 in 1831, and 1811 in 1841.

Divisions for Ecclesiastical and Legal Purposes.—Yorkshire is in the archiepiscopal province of York, and until recently the whole county, with the exception of the Western Riding, was entirely in the diocese of Chester, was entirely in the diocese of York, in which it formed the archdeaconries of York, or the West Riding, comprising the deaneries of the city and Ainsty of York, Craven, Doncaster, and Pontefract; of the latter, which was founded an order in church by the Duke of St. George, and is situated in the diocese of York, and is situated in the diocese of the county, according to the statement given on the authority of the Population Returns for 1841, under the head of Statistics, is 623; but earlier authorities make it only 604, of which 180 are returned as 223 vicarages, and 123 perpetual curacies, according to Lewis's Topographical Dictionary of England. The ecclesiastical divisions of the county have been recently much altered, for the formation, under the Act of Parliament, dated October 5, 1836, of the new bishopric of Ripon, which was established by consent of the archbishop of York and the bishop of Chester, and which consists of all that part of the county which formerly belonged to the diocese of York, and of the deanery of Ripon, consists of a populous district in the West Riding, and of parts of the deaneries of the city and Ainsty of York, and of the dioceses of the county is divided between the dioceses of York and Ripon, which are subdivided as follows: The diocese of York consists of the archdeaconry of Craven, comprising the deaneries of the city and Ainsty, the liberties of the county, and the diocese of Ripon, containing the deaneries of Bilsdale, with 87 benefices, and of Doncaster, with 95 benefices, to the East Riding, containing the deaneries of Bilsdale, with 30 benefices, and Stockton, with 26 benefices, with 72 benefices, and of Cleveland, with 62 benefices, of the division of the county is divided between the dioceses of York and Ripon, which are subdivided as follows: The diocese of York consists of the archdeaconry of Craven, comprising the deaneries of the city and Ainsty, the liberties of the county, and the diocese of Ripon, containing the deaneries of Bilsdale, with 87 benefices, and of Doncaster, with 95 benefices, to the East Riding, containing the deaneries of Bilsdale, with 30 benefices, and Stockton, with 26 benefices, with 72 benefices, and of Cleveland, with 62 benefices, of the division of the county is divided between the dioceses of York and Ripon, which are subdivided as follows: The diocese of York consists of the archdeaconry of Craven, comprising the deaneries of the city and Ainsty, the liberties of the county, and the diocese of Ripon, containing the deaneries of Bilsdale, with 87 benefices, and of Doncaster, with 95 benefices, to the East Riding, containing the deaneries of Bilsdale, with 30 benefices, and Stockton, with 26 benefices, with 72 benefices, and of Cleveland, with 62 benefices, of the division of the county is divided between the dioceses of York and Ripon, which are subdivided as follows: The diocese of York consists of the archdeaconry of Craven, comprising the deaneries of the city and Ainsty, the liberties of the county, and the diocese of Ripon, containing the deaneries of Bilsdale, with 87 benefices, and of Doncaster, with 95 benefices, to the East Riding, containing the deaneries of Bilsdale, with 30 benefices, and Stockton, with 26 benefices, with 72 benefices, and of Cleveland, with 62 benefices.
and Riddell, with 34 benefices. The dioceae of Ripon consists of the archdeaconry of Craven, containing the deaneries of Craven, with 33 benefices, and of Pontefract, with 153 benefices; and that of Richmond, containing the deaneries of Boroughbridge, with 35 benefices, Richmond, with 34 benefices, Catterick, with 42 benefices, and Kirkby Lonsdale, with 10 benefices. According to the above details, which are derived from Coxe's 'Clergy List,' for the years 1831 and 1832, and from information collected from the records of some old benefices and the establishment of some new ones, it would appear that the total number of benefices in the diocese of York, which is now confined within the limits of the county, is about 525, and the number in the diocese of York, including the dioceses of Beverley, about 508, making a total for the county of about 832 benefices.

Yorkshire is in the northern circuit, and the assizes are held at York. The quarter-sessions for the city are held at York, those for the East Riding at Beverley, those for the West Riding at Wakefield, and those for the North Riding as follows:—The Easter sessions at Pontefract, the Midsummer at Skipton, Bradford, and Rotherham; the Michaelmas at Knaresborough, Leeds, and Doncaster; and the Christmas sessions at Knaresborough, Wakefield, and Selby.

The county gaol is at York, the house of correction for the North Riding at Northallerton, that for the East Riding at Beverley, and that for the West Riding at Wakefield. There are other houses for York, Richmond, Beverley, Hull, Leeds, Bradford, Knaresborough, Ripon, Pontefract, Rotherham, Doncaster, Halifax, Sheffield, and Rothwell.

It is a distinguishing peculiarity in the civil and military jurisdiction of Yorkshire, that each of the three Ridings has its ancient lord-lieutenant. The Ainsty, which was formerly a wapentake of the West Riding, but was annexed to the city of York, and placed under its jurisdiction in the 27th year of Henry VI., is considered part of the North Riding for parliamentary purposes. Although in the Population Return it is styled a wapentake of the West Riding; and the separate jurisdiction of the liberty of St. Peter of York, which comprehended all those parts of the city and county that belong to the cathedral church of St. Peter at York, and are situated within the Populous and Army, according to the Census of 1841, comprises 51 places in the East Riding, 42 in the North Riding, 25 in the West Riding, and 7 in the Ainsty, was abolished by the Act for reforming municipal corporations, 6 and 6 William IV., c. 76. Each Riding had formerly a separate judicial power, and its justices held their courts of quarter-sessions at York, and exercised civil and criminal jurisdiction over every place within the liberty, however distant it might be from the city. No commission of the peace is now granted, and civil and criminal courts are neither justices nor quarter-judges nor quarter-justices for the liberty. Sessions for the archbishop's liberty of Cawood, Wislows, and Otley are held quarterly at Otley, in January, April, July, and October.

The county of York antiently sent two members to parliament from the boroughs of Skipton, Otley, and Ripon, and the union abolished by that Act was 32; the numberness of the county will be found under the head of Statistics.

History and Antiquities.—At the time of the invasion of Britain by C. Julius Caesar, this part of the island, together with the neighbouring counties in the north of what is now Yorkshire, was called by some from the uncertainty of the most numerous and powerful of the ancient Britons, and the last to submit to the Romans. The Roman power was not established in this district until the time of the emperor Vespasian; and, when the year 40 A.D. of our era was added to our Christian era, there were only a small number of forts in this part of the island. After a century later, about the year 120, the emperor Hadrian visited Britain, and in consequence of the frequent incursions of the Caledonians into the northern district of Roman Britain, he formed a wall or rampart of earth and timber from the River Tyne at Pontefract to the River Forth near Edinburgh, which place had been his head-quarters in the west. This part of the island had its share in the numerous estates which followed between the Romans and the new Britons. The emperor Constantius Chlorus resid at a considerable time at York, and died there in May of the year 337; and his son Constantius, commonly called Constantine the Great, was proclaimed emperor at that city in 307. Between that time and the final withdrawal of the Roman forces from Britain in the 5th century, the territory of the province was subject to numerous invasions from the northern tribes, and the change of its inhabitants aggravated the anarchy and confusion of this part of the Roman empire. According to Richard Carew, whose account of the Romano-British province of Yorkshire is one of the best, the city of York was for a time the head-quarter of the kingdom of the Mercians, if not entirely, to the province of Maxima Censoria, and was inhabited by the Brigantes and the Picts or people of the East Riding.

Being chosen by the Romans as an occasional rendezvous, and as a market-place for the country, York and the surrounding country were supplied with many marks of their power and skill. They bestowed extraordinary attention upon the public roads of this district, which considerable roads exist even at the present time, and which indicate the presence of considerable settlements and populous districts. One of the roads of which the names are legible, is the New Hean or Yoredale road, which, under the name of the Wathing or Water Street, extended along the whole length of England from Rutupia (Richborough) in Kent to the wall of Scaesurae entered the county from Nottinghamshire and Chester, to York, and passed through Baines near Grassendale, over Scarsby and Ripburg to Barnsley, through Pontefract to Castleford, a little below the junction of the Wharfe and Calder, from which point the road was continued by Tadcaster to York. 'From this city,' says Herring, 'at York, wye dwell, the north-east road of the Ouse, crossing that river near Aldborough or Boroughbridge, and thence by Leeming Lane to Untedbridge (adjoining to which vestiges of Caractacum are to be seen), where, turning more to the north, we passed into the county of Durham.' Another military road led from Newcastle, now Manchester, to York, and passing by Saltburn, the five miles south of Malton, and Almondbury, about five miles south-east of Huddersfield, crossed the Pennine Escarpment by a mile-long Devil's Bridge, and passed through the present turnpike-road to Wakefield, whence it continued in the direction of the present road about half a mile to Pontefract, and then, turning to the left, in a military way for some miles to Wakefield, a mile north-west of which place the principal were—2 miles from Castleford by Selby, Barnsley, Emehurst, and Ackworth, to the Wakefield site or area of Pontefract; a road which appears to have passed through Pontefract a mile west to the vicarage of the parish of Wakefield, Wombwell, Stannington, Campell, and Hattfield, and also to have ri
fended northward to Castleford; a road from York in continuation of the route from Manchester to that city, proceeding to Malton, and then dividing into two branches, of which the first, which is now called Wake's Causeway, and a portion of which is in excellent preservation, twelve feet broad, paved with flint pebbles, and in some places raised more than three feet above the surface of the ground, led to Dunesty Bay (the Dunus Sinus of Poltemy), near which a fort was built. The second branch, the old road from York over the Wolds to Bridlington Bay, with a branch towards Humberside; and a road leading towards Patrington and the Spurn Point, which likewise branched from the last mentioned at Stamford Bridge, and from which, at the southernmost end of that place, Spurn Street extended southward to the village of Brough, on the Humber, opposite to Wintringham in Lincolnshire, whence a Roman road proceeded southward to Lincoln. Traces of Roman encampments, as Druidical or of the Tadcaster sort, have been discovered in several parts of the county; and Roman antiquities have been discovered in many places, especially in York and its vicinity. Tumuli and Druidical remains are also found in several places. The Wolds contain many of the former; and of the antiquities supposed to be Druidical may be mentioned a curious assemblage of rocks called Brannam Craggs, about nine miles west of Rippow, on which indications of rude sculpture are supposed to have been a Druidical temple, and, at the same place, a well called the Devil's Arrows, near Broughbridge, which some suppose to be Druidical, and others of Roman origin. The principal Roman stations were at Eboracum, now York; Cataractonium, or Cataractonum, now Cawthorpe; Elborough, near the seat of the earl of York; Durobrivium, both in Yorkshire, and not far from Halifax; Jarrow, at Aldborough; Ely, a little below the junction of the Aire and Calder; Danum, at Doncaster; Olicana, or Olicum, at Selby; Calleva, at Teddington; Dereventum, at Stamford Bridge and Selby; and Skipton, in the middle of that place, by which the Roman road passed from Skipton, in Westmorland, to York. A few other stations are marked on the Map of Ancient Britain, published by the Society for the Diffusion of Useful Knowledge, which also indicates the probable line of the Roman roads.

All that is known of the state of Yorkshire shortly after the termination of the Roman dominion is that it formed part of the British kingdom of De light, Deirca, or Deira, the name of which, as well as that of Els, one of its kings, an Anglian form of Athelstan, is well known in connection with the circumstance which is said to have induced Gregory to send St. Augustine and his companions as Christian missionaries to Britain. The boundaries of the Saxon and subsequently the Danish kingdom of York are not accurately known. They varied frequently with the fortunes of war, but it generally included the greater part of Yorkshire; and Baines observes that the Villa Regia, the seat of the Northumbrians, is conjectured to have been at Osmundburn on the northern bank of the River Derwent. Of the events connected with the subsequent contests for the sovereignty of Deira, and the establishment of the Danish power there, are described in the article above referred to, where also will be found sufficient details of the history of this district down to the time of Harold, the last of the Anglo-Saxon kings. During his reign his brother Tostig invaded his dominions under the circumstances detailed under Harold II., vol. xii., pp. 51, 52, and was defeated by him in September, 1066, in a great battle near Stamford Bridge, after which the victorious Harold returned to York, and was received with the first intelligence of the invasion of William of Normandy. Of the events which followed his victory at Hastings, so far as they relate to this county, some particulars are stated under Yorke, which city suffered dreadfully in the struggle between the Normans and the Danes, and afterwards with Northumbria, together with the Danes, whose assistance they had called in. So dire was the vengeance of William, that for the space of many years after his successful victory over the surrounding country lay totally uncultivated, becoming the haunt of robbers and beasts. Yorkshire is called Eurewicshire in the Domesday Survey, and appears then to have comprised very nearly its present limits. It had been previously, during the Saxon dominion, subdivided into three ridings, or, as they were originally called, trithings.

In the year 1138, during the reign of Stephen, the north of England, as far as York, was invaded and ravaged by David, king of Scotland, who was defeated near Northallerton, and returned to the north; and on his return, having been bribed by the neighbouring barons, who had been summoned by Thocto, the bishop of York, under the command of Ralph, bishop of the Orkneys, Walter l'Esée, and William de Albemarie. One of the next important events in the history of the county was the capture of the fugitive king by the inhabitants of York in 1141. The same year saw the capture of the favourite of Edward II., in Scarborough Castle, where he was taken prisoner by the earls of Pembroke and Warren. In 1318 the northern part of the county was ravaged, the towns of Northallerton, Boroughbridge, Scarborough, and Ripon, and many other places were pillaged, by the Scots under Douglas, who escaped to Scotland with an immense booty and numerous prisoners. In the following year another invasion of the Scotch, under the earl of Murray, advanced as far as York, and set fire to some houses in the city. In the same year the archbishop of York, that he, accompanied by the bishop of Ely and a great number of clergymen, collected an army of about 10,000 men, and pursued Murray as far as Myton on the river Swale, about twelve miles from York, where the Scotch were defeated and the king was taken prisoner. The city was threatened with a second invasion by the Danes, at York, and the inhabitants were thoroughly routed. From the number of clergy killed on this occasion, the engagement received the name of the White Battle. Shortly after, in 1321, Thomas, earl of Lancaster, and the husband of the lady Devereux, or Devereux, a sister of John, bishop of Ely, who took arms against Edward II., was defeated and taken at Boroughbridge; and he, with several of his party, was shortly afterwards beheaded at Pontefract. In 1347, taking advantage of the absence of Edward III. in his continental wars, David Bruce led a Scottish army into England, and devastated the country as far as York, where he was checked by the forces of Queen Philippa, whose court was then at York: and who, marching in person with her army against Bruce, brought him to battle at Neville's Cross, near Durham, where he was defeated. Yorkshire formed also the scene of many interesting events during the struggle between Richard II. and Bolingbroke, who eventually became king under the title of Henry IV.; and who, in 1399, on his return from banishment, landed at Scarborough, where he was received with the usual marks of respect and solemnity. Bolingbroke, which has but which has long since been washed away by the sea. He was immediately joined by several of the powerful northern barons, and he marched westward, by Hull, where he was refused admittance, towards Doncaster, where he landed on the metaphysical school. Robert of Devereux, who was assumed the crown, the deposed Richard II. was confined, successively, in the castles of Leeds, Knaresborough, and Pontefract, from the latter of which, after his death, his body was removed to London. In 1406 one of the conspirators, formed for the purpose of recovering the crown for King Henry, the son of Henry IV., and the brother of Henry V., was captured, and, with several other barons, was headed by Scroop, archbishop of York; but, though they collected a large body of troops to their rendezvous at York, Scroop and some others of the leaders were at last surprised and put to death by a force of hot, in the absence of Henry V., under the command of Ralph Nevill, earl of Westmorland, who com-
manded the troops against them; and the insurrection was thus stopped by their being taken prisoners, and afterwards beheaded. Percy escaped on this occasion, but in February, 1468, being again in arms, he was defeated and slain at the battle of Brannam Moor, near Newcastle, by Sir Thomas Rokeby, the sheriff of Yorkshire. During the long war between the houses of York and Lancaster this county was the scene of several remarkable events, among which was the defeat of Richard, duke of York, by the forces of the House of Lancaster, under Edward of Warwick, at Fishlake, in 1468, at the battle of Wakefield, in which he lost his life. His son, Edward, IV., attacked the forces of Henry VI., or rather of Margaret, in the following year, in this county, after the battles of Mortimer's Cross and Bernard's Heath. Having reached Pontefract, where he received the promise of surrender from the towns of York, Wakefield, and a small south of Tadcaster, where he routed the Lancastrian forces with a slaughter extraordinary even in that sanguinary war. The fugitives attempted to escape by Tadcaster-bridge, but being so closely pursu'd and pressed to reach it, they were overtaken and killed with such precipitation that the bodies of those drowned in the attempt formed a bridge for the passage of the survivors. The total number slain on this occasion is reported to have been 36,776, including many leading citizens, the result of which was that Henry and his queen fled to Scotland, while Edward advanced and took possession of York. Events having once more turned in favour of Henry, Edward fled to Holland in 1469; but on the 1st of July, 1470, in the following year, he returned to land, landed at Ravenspur with 2000 men, and, being well received, proceeded to York, where he planted a garrison, and thence marched southwards towards London, and won the battle of Barnet, which established him on the throne.

In the history of Yorkshire during the reign of Henry VII. was the raising and defeat of an insurrection of the northern counties against a land-tax which had been imposed for the support of the army, and in the proposal of which the earl of Northumberland was suspected of having taken an active part. Topcliffe, near Thirsk, was assailed by the insurgents, who killed him and many of his servants; but the insurrection was eventually put down by the earl of Surrey, and several of the leaders, among whom was John A'Chambre, were executed at York. After the defeat of Northumberland, however, he took a different route, arrived at York. Contrary to the advice of the marquis of Newcastle, Prince Rupert, York on the 2nd of July, to give battle to the parliamentary army, by which he was compelled to retreat. The marquis of Mantua, who had more than his lives and civil rights lost, chiefy the roads, and the parliamentary forces obtained possession of more than 100000 men, soldiers, and the artillery and stores of Rupert's army. The remnant of which soon escaped to Lancashire, and the marquis of Newcastle fled to the Continent. The parliament soon afterwards obtained possession of York, and several engagements were fought in the vicinity of the city, and the siege of the castle was raised on the 25th of June. In the following year, 1472, Scarborough also the royalists made a vigorous and protracted defence, but both town and castle at last yielded to the besieging forces. The town was taken on the 29th of March, 1489. Colonel Morice was again taken for the king by Colonel Morice, and endured a third prolonged siege, which, for a time, was threatened, but was finally surrendered on the 25th of March, 1449. Colonel Morice was again taken for the king by Colonel Morice, and endured a third protracted siege, which, for a time, was threatened, but was finally surrendered on the 25th of March, 1449.
the king in September, 1648, but about three months afterwards its final siege by the parliamentarians was terminated by the surrender of the garrison, the troops having been summoned to return.

Of the subsequent history of the county the leading events are— an insurrection raised in the West Riding, in the year 1663, by a body of misguided people, led by old parliamentary soldiers and others disaffected to the restored government, the list of whom, with the troops and militia, who attacked them in Farnley Wood, near Otley, and took many prisoners, of whom twenty-one were executed; the raising, during the rebellion of 1745, of four companies of foot, supported by the inhabitants of the county, on the command of government; the garrisoning of the towers, in several parts of the county, occasioned by the introduction of new and obnoxious regulations respecting the levying of the militia; and serious disturbances, occasioned chiefly by the distracted state of the manufacturing districts, in the winter of 1822, during which period, in the summer of 1842, although the more serious outbreaks on the latter occasion were confined to Lancashire.

Among the more remarkable antiquities of Yorkshire, excepting those of the city of York itself, are the remains of the castle of the Earls of Durham, in the parish of Tadcaster; a great number of castles, a few of which are still standing, and the walls of which are of enormous thickness, and which formerly covered seven acres, although now but few remains of them have been left. The castle of York, which was built by Serlo de Burgh, who accompanied William the Conqueror from Normandy; Pontefract castle, the walls of which are of enormous thickness, and which formerly covered seven acres, although now but few remains of them have been left; the castle of Helmsley, Malton, Malton, Pickering, Richmond, Skipton, Sheriff Hutton, and Skelton; whose remains are somewhat similar to those of Pontefract; and the tower of the Percy family, known as the ancient seat of the Percy family. There are also a few ancient mansions in the county which remain tenable, among which are Temple Newsome, near Leeds, and Whittington, near Helmsley; while the remains of many modern mansions in the county, especially in the West Riding, is also considerable.

The county of York contained, according to Burton's Map (1589), of Ecclesiastical History of Yorkshire; amongst 100 large houses of which 12 were abbey, 44 priors, 7 alien priors, 13 cells, and 28 houses of various orders. There were also three priories and three commanderies in the county. Of the several ecclesiastical establishments many ruins yet exist, of which are exceedingly beautiful. The principal remains of abbey are those of St. Mary's, at York; of Fountains, Kirkstall, Roche, and Selby, in the West Riding; of Ryedale, Kilwinning, and Whitby, in the North Riding. Among the priories are those of Knaresborough and Helmsley. Of the existing abbey churches, those of Knaresborough and Helmsley are of the most interest. There are villages and towns in the county of York.

YORK.

The English counties were divided into the West Riding, the East Riding, and the North Riding. The West Riding is the richest and the most populous part of the county, and contains the city of York, the largest town in the county. It is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses. The West Riding is the most northerly of the three divisions of York, and is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses. The West Riding is the most northerly of the three divisions of York, and is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses. The West Riding is the most northerly of the three divisions of York, and is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses.

The West Riding is, in the English counties, the most northerly division of the county of York. It is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses. The West Riding is the most northerly of the three divisions of York, and is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses. The West Riding is the most northerly of the three divisions of York, and is bounded on the north by the river Ouse, and on the south by the river Don. It is a large and fertile district, with a rich soil, and is noted for its fine cattle and horses.
edge-tools, and grindery in large proportion, makers of files, fire-tools, fenders, forks, table-knives, hall-pressers, knife-blades, mauls, razors, razors-smiths, razor-case makers, ring-makers, saw-smiths, scale-cutters, makers of scissors and shears, seythe-grinders, sheer-steel and sheer-makers, silversmiths, silver-platers, spade-makers, spring-knife grinders, steel-casters, steel-forgers, steel-burners, rollers and makers of steel, stove-grate makers, tilters, turners in wood and ivory, and all kinds of white-metal smiths, numbering all 11,600; and at Bradford and Eccles-field are about 1000 men employed in similar occupations. Carpets are made at Dewsbury, and glass and earthenware at Wakefield and other places; and about 200 nailers find employment at Darton and its vicinity.

The East Riding would be entirely agricultural, if the town of Kingston-upon-Hull (with its suburb Seaboe) did not contain the manufactures indispensable at an active sea-port, about 1900 being there employed in making ropes, sail-cloth, and sailing, and in preparing colours. Boilers for steam-engines are also made at Hull, but this manufactury is on a very limited scale.

The City of York contains nearly 200 men employed in linen manufacture, and eighteen comb-makers; the brush-makers are entered above under handicrafts.

The North Riding may be deemed entirely agricultural, the manufacturers inserted in the list being weavers of linen yarn, which seems to be entirely the product of domestic manufacture. There are many makers of much scattered swords at Hutton, 73 at Appleton-upon-Wiske, 62 at Osmotherley, 48 at Northallerton, 27 at Thornaby, 23 at Barnby, 22 at Sowerby, 21 at Burton-upon-Yare, and 20 at Broughton. At Starforth is a very limited manufacture of carpeting; at Whitley in Whitley-Sands, and about 90 men are employed in making sail-cloth and sack-cloth, and 17 in the delicate manufacture of jet ornaments.

If the registered baptisms, marriages, and deaths bore the same proportion to the actual population as in 1801, the population of Yorkshire, in the under-mentioned years, would have been as follows:—

The following table distinguishes the number of births—

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1801</td>
<td>276,647</td>
<td>268,635</td>
<td>55,334</td>
<td>76,266</td>
</tr>
<tr>
<td>1811</td>
<td>296,606</td>
<td>289,276</td>
<td>56,435</td>
<td>77,419</td>
</tr>
<tr>
<td>1821</td>
<td>316,610</td>
<td>286,398</td>
<td>58,490</td>
<td>78,030</td>
</tr>
<tr>
<td>1831</td>
<td>337,818</td>
<td>330,780</td>
<td>60,106</td>
<td>79,703</td>
</tr>
</tbody>
</table>

From 1801 to 1841 the population of the West Riding increased 588,819, or 104 per cent.; the East Riding, 83,944, or 75 per cent.; the North Riding, 48,307, or 51 per cent.; and the City and Ainsty, 13,928, or 54 per cent. The total increase of the whole county was 757,066, or 62 per cent. In the three years ending June, 1841, the proportion of marriages to the population was as under:—

<table>
<thead>
<tr>
<th>Marriage Rate</th>
<th>West Riding</th>
<th>East Riding</th>
<th>North Riding</th>
<th>England</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of Marriages</td>
<td>1 in 1222</td>
<td>1 in 1107</td>
<td>1 in 136</td>
<td>1 in 127</td>
</tr>
</tbody>
</table>

In the same three years, the proportion of persons married under 21 years of age was: West Riding, 20:57; men, 7:43; East Riding, 18:57; men, 3:03; North Riding, 16:00, or 3:57. The Census Returns of 1841 give the birthplace of the population: the following is an abstract:—

The number of foreigners and British subjects abroad was, in the West Riding, or 1 per 1000; East Riding, 431, or 2 per 1000; in the North Riding, 240, or 5 per cent.; and in the Ainsty, 5, or 0.005. The proportion of persons whose ages were not specified was 2 in the West, 10 in the East, and 5 in the North Riding and Ainsty. The immigration into the West Riding is not less than in other counties where manufacture is predominant; but if the East and North Ridings have distinct counties of themselves, with a different name, the real extent of immigration into the West Riding will then be shown.

The number of persons to a square mile in 1841 was 446 in the West, 174 in the East, and 93 in the North Riding, and about 445 in the City and Ainsty. The Population Returns for 1841 the number of parishes to be 186 in the West, 197 in the East, and 192 in the Ainsty, and 48 in the City and Ainsty; and the position is separately given for 728 squares in the West, 409 in the East, and 603 in the North Riding; for 75 places in the City and Ainsty. The population of each hundred and borough, in 1841, for each of the parishes of the county, is shown in the following tables:—

West Riding.

### City, and Ainity of the City of York.

| CITY AND AINITY | HOUSES | PERSONS | AGES | PERSONS BORN |
|——— |——— |——— |——— |——— |
| York City | 2,790 | 7,720 | 18,810 | 14,390 | 14,390 | 28,780 | 14,390 | 14,390 | 14,390 |
| York (City of) | 49,720 | 1,947 | 11,783 | 1,479 | 1,479 | 2,958 | 1,479 | 1,479 | 1,479 |
| Total | 52,510 | 7,760 | 18,810 | 14,390 | 14,390 | 28,780 | 14,390 | 14,390 | 14,390 |

### Grand Totals

| PERSONS BORN |
|——— |
| 3,669,510 | 216,060 | 25,352 | 2,075 | 788,592 | 802,667 | 1,591,480 | 390,150 | 399,306 | 408,542 | 423,351 | 1,462,496 | 159,541 |

The number of inhabited houses, &c. in 1831 was as follows:—

| COUNTY | Expenses, Crime, &c.—Sums expended for the relief of the poor:—1789-1830 (annual average), West Riding, 20,218; East, 4,110; North, 683; in 1776, West Riding, 50,060; East, 11,095; North, 12,734; in 1783-4-5 (average), West Riding, 66,065; East, 15,499; North, 18,669. The sums expended in the following years and the rate per head are given in the subjoined tables.— |
|——— |——— |
| W. Riding | E. Riding | N. Riding |
| Inhabited houses | 100,480 | 32,681 | 29,160 | 10,404 |
| Families | 198,464 | 36,960 | 40,760 | 7704 |
| Houses building | 1,676 | 298 | 117 | 74 |
| Houses uninhabited | 12,147 | 1,970 | 2,026 | 453 |

Between 1831 and 1841 the number of inhabited houses in the whole county increased from 15,591 to 15,998 (by 1260) inhabitants; and the number of persons to each house averaged 50 instead of 51. The total increase of houses was 18 per cent.
The proportion in 1841 of the total number of paupers to the total population was 8 per cent. in each Riding which is per cent. less than the average for England. In the West Riding there were 664 lunatics and inmates chargeable on the poor-rate in August, 1842; in the East Riding 173; and in the North Riding 144. In 1834 there were 3873 bastard children in the West Riding chargeable on the poor-rate; in the East Riding 167; in the North Riding, 1506; being respectively 1 in 221: 1 in 130; and 1 in 127 of the total population: in England the proportion was 1 in 215. The number of illegitimate births in 1834, in the West Riding, was 1534; or in the total number of births in that year: in the East Riding 292, or 1 in 17; and in the North Riding 430, or 14: the proportion for England being 1 in 20. The number affiliated in 1834-5, in the West Riding, was 75: in the East Riding 212; and in the North Riding 32. In 1855-6 there were 405 affiliated in the West, 20 in East, and 184 in the North Riding. In 1839-40 the number of illegitimate children registered in the West Riding was 3382, or 3-4 to 1000 inhabitants: in Notts and Herefordshire (which were the other counties that made a return) the proportion was 9-1000.

The three Ridings contribute to the expense of improving
ork Castle and to all asseze expenditure in the following
otions for every ten, namely, West Riding, 12s.;
est Riding, 3s. 6d.; and North Riding, 4s. 6d.
he particulars of the county expenditure in 1834 are
os follows:—

<table>
<thead>
<tr>
<th>Wm. Riding</th>
<th>E. Riding</th>
<th>N. Riding</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>total expenditure</td>
<td>£21,295</td>
<td>£30,803</td>
</tr>
</tbody>
</table>

The number of turnpike trusts in the whole county, in 1810, was 120; the income from tolls, 171,822l.; parish impositions in lieu of statute duty, 365l.; and total income, 201,438l., including 20,538l., borrowed on security of lands. The total expenditure for the year was 97,097l., including a debt of 11,424l. paid off, and 23,333l., or improvements. The bond and mortgage debt amounted to 955,325l.; the sum of 163,543l., remained as unpaid interest, making, with floating debts and balances due to treasurers, a total debt of 1,225,062l. In 1836 the debt hadfallen to 5-0 years' income; for the whole of England the proportion of income to debt for 45 years: the proportion of unpaid interest to the total debt was 11 per cent.; in England 12 per cent.
The following is an analysis of the church-rate returns:

<table>
<thead>
<tr>

<td>8,100</td>
<td>4,264</td>
</tr>
</tbody>
</table>

The total expenditure is £21,295, £30,803, £30,125.

In 1841 the proportion of persons committed, to the total population of the county, was 1 in 944; in England and Wales, 1 in 568. The commitments for 1842 are excluded from the average given above, as the numbers were swollen to the amount of 192 by the outbreak which occurred in the manufacturing districts; but even with this deduction the number of offenders in 1842 was nearly twice as great in 1836. The incidence of crime was consequently in four years from 1839 to 1842 inclusive, though the proportion is still below that of many counties. The commitments for each Riding cannot be given separately.

Of 2296 offenders (2218 males and 88 females) tried at the assizes and sessions in 1842, there were 153 charged with offences against the person; 273 with offences against property committed with violence; 1836 (including 1318 cases of simple larceny) with offences against property committed without violence; 8 with malicious offences against property; 50 were charged with forgery and counterfeiting base coin, and 270 with various misdemeanours, including 192 for riot, sedition. Of 1894 persons convicted, 2 were executed for murder; and of 9 others, against whom sentence of death was pronounced, 1 was transported for a long term, and 8 for life; and 2 others were also sentenced to transportation for life; 1 for above 15 years; 75 for above ten and not exceeding fifteen years; 100 for above seven and not exceeding ten years; and 118 for terms of eight years. The numbers transported were as follows:

- 1842: 157
- 1843: 133
- 1844: 9
- 1845: 6

The proportion of provinces committed in the county, on an average of several years, was 93:8 per cent.; in England and Wales, 89:3 per cent.

Savings Banks. There are thirty-four of these institutions in the county: the number of depositors to the total population is 1 in 26; and there is 1 depositor under 20l. to 48 persons; the proportion in both cases being rather low. The average amount invested by all classes of depositors was 31l. 19s. in England, 31l. The number of depositors and amount of deposits in each of the following years were as follows:

<table>
<thead>
<tr>
<th>1806</th>
<th>1807</th>
<th>1808</th>
<th>1809</th>
<th>1811</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deposits</td>
<td>£7,213</td>
<td>£9,618</td>
<td>£12,902</td>
<td>£12,419</td>
</tr>
</tbody>
</table>

The distribution of the sums invested in 1839, 1840, and 1841 is shown in the following table:

<table>
<thead>
<tr>
<th>1839</th>
<th>1840</th>
<th>1841</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deposits</td>
<td>£6,001</td>
<td>£6,025</td>
</tr>
</tbody>
</table>

The deposits of 747 Friendly Societies, not reckoned above, amounted in 1842, to 100,110l.; and 31,254l. were invested by 604 charitable institutions.

Elecitive Franchise. The actual number of county voters registered, in 1839, in the West Riding was 29,456; in the East Riding, 7965; and in the North Riding, 2913; and in 1839-40 the number of each class registered in the three Ridings were as under:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

At Beverley there were 635 freemen; at Hull, 1668; Malton, 10; Scarborough, 6; and York, 2497.

**Education.**—Summary of Returns made to Parliament in 1833.—Sunday-schools returned from places where no other school existed; in the West Riding 34, scholars 2145; East Riding 8, scholars 275; North Riding 6, scholars 161; in the City and Ainsty all children attending Sunday-schools had the opportunity of attending other schools also. Sunday-schools, which were also duplicate schools: in the West Riding 77, scholars 5392; East Riding 35, scholars 2724; North Riding 34, scholars 2223; City and Ainsty 11, scholars 814: in the case of these schools duplicate entry was known to have taken place. Boarding-schools in the West Riding 91; East Riding 18; City and Ainsty 6: the scholars are included in the table below. Lending libraries were attached to 255 schools in the West Riding; 41 in the East Riding; 31 in the North Riding; and 15 in the City and Ainsty. The number of children returned as attending both Sunday and daily schools was as follows; but except in the cases above mentioned the extent of duplicate entries cannot be ascertained:

<table>
<thead>
<tr>
<th><strong>Schools</strong></th>
<th><strong>scholars</strong></th>
</tr>
</thead>
<tbody>
<tr>

<th><strong>scholars</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Infant</td>
<td>14049</td>
</tr>
<tr>
<td>Daily</td>
<td>70632</td>
</tr>
<tr>
<td>Total</td>
<td>214,423</td>
</tr>
</tbody>
</table>

On an average of three years ending June, 1831, the number of persons married who signed the register was 32,212 for men, and 25,918 for women. In the East 19 and 41; and in the North Riding 23 and 40 for women. The superiority in the East and North Riding may be attributed to the large number of children (more than one-half) attending daily while in the West Riding the proportion, according to returns of 1833, was but one-third.

**YOUGHALL, or YOUGHAL, is a sea-port town, and a parish in the county of Waterford.**

Youghall is a town of remote antiquity, and it is said that the town was once a seat of a bishop, and that the town was the headquarters of the last battle of the Irish, which was fought in the year 1579. The town has since been the seat of a bishop, and the cathedral of that see is still preserved in the town.

The present Statistics of Education in York and Hull are given in the *Journal of the London Statistical Society,* the inquiry at both these places was undertaken by the Manchester Statistical Society. In 1843 Mr. Edward Baines, jun., of Leeds, undertook an elaborate inquiry into the state of elementary education in the manufacturing districts of the West Riding, the results of which he published in a short pamphlet.

- The number of joint and duplicate qualifications was estimated at 4518, or 15 per cent. on the total number.
- In this total number was added the following qualifications: - Freehold and copyhold 29; freehold and incomplete, leasehold and incomplete, freehold and leasehold, 867; qualifications where the tenure was not mentioned 98.

Mr. Baines's inquiry extended to parishes and townships, comprising a population of 844,563, according to the census of 1841. The proportion of Sunday scholars was found to be 1 in 5 of the total population, and 50 per cent. of the scholars were capable of reading the Scriptures. The number of scholars in daily and Sunday schools was 10 per cent. under the number given below as attending such schools. The following is an abstract of Mr. Baines's tables:

<table>
<thead>
<tr>
<th><strong>Schools</strong></th>
<th><strong>scholars</strong></th>

According to the Report of the Corporation Commissioners, Youghall is supposed to be a borough by prescription. Besides the supposed charter of King John, previously mentioned, the town received, according to the above authority, three charters from Edward III., three from Richard II., one from Henry IV., two from Henry V., one from Edward IV., two from the reign of Richard III., one from Henry VII., three from Elizabeth, two from James I., one from Charles II., and one, which was not considered valid, from James II. The first charter of James I., granted in 1609, was the governing charter until the corporation was dissolved long, in 1830, by an Act of the Irish Repeal. The second charter was a regulation of municipal corporations in Ireland, in which Youghall was placed in Schedule B., or among towns which had the option of obtaining new corporations. The title of the dissolved corporation was: Burgesses, Burghers, and Commonalty of the town of Youghall; and the annual income amounted to about 114l. 8s. Id. of which 46l. 8s. Id. consisted of rents of land and buildings; 400l. was an annuity from the Blackwater Bridge Company, before 1824, and has been paid into the union fund; 30l. is the share of the ferry, and about 30l. from tolls and customs.

The right to the election of members of parliament, as well as the existence of the borough, appears to rest on prescription, but members have been sent ever since the year 1174, when one was sent to London until the Union, at which time there has been but one. The constituency was altered and extended under the Irish Reform Act, and the number of voters registered at the beginning of 1833 was 233.

From a mile and a half north-east of the town, the Blackwater is crossed by a light and elegant timber bridge, which connects Youghall with the county of Waterford. It was erected in 1830, at an expense of 25,000l. exclusive of 8500l. to the corporation for the ferry. This bridge is 172 ft. long, including a drawbridge of 40 feet, and is 16 ft. wide between the railings; and it is supported by 57 sets of piers or pillars.

It was formed by a company, to whom government advanced 10,000l. by way of loan, but the speculation has not proved remunerative. Among the interesting objects in the vicinity is a meadow called Myrtle Grove, which some say was erected, and which doubtless was for a considerable time inhabited, by Sir Walter Raleigh, in 1596. Raleigh was mayor of the town in 1588, and it is said that he was there after the death of Sir Walter Scott, and that the first potatoes brought by him from America were planted.

In Hall's 'Ireland,' however, it is stated that the house, which is still standing, though somewhat modernized, is said to have been originally the residence of the ware- ders, or bailiffs of the manor, and to have been altered to the character of an English manor-house by either Sir George Carew or Sir Richard Boyle, both of whom resided there. Of the other residences in the neighbourhood may be mentioned College House, a handsome mansion, belonging to the college of the University of Dublin; and near the site of an ancient house built in 1464, which has been taken down. The gates of the town have been removed, excepting one which is very dilapidated, and another which has been rebuilt; and there are still one of the ancient round towers, and considerable remains of the old wall, especially on the western side of the town. There are several ancient houses in the town and neighbourhood, among which are Tynte's castle, in the main street, and the remains of Kilrudder Castle, on the river Toragh, at the south-west end of the town. On the north-west side of the town are remains of a Danish fort, which appears to have been of great extent. Near the town are two chalybeate springs, which are but little used.

Reports of Irish Boundary Commissioners, and of the Commissioners on Municipal Corporations in Ireland, Population Returns, and other Parliamentary Papers; Lewis's Topographical Dictionary of Ireland; Archdall's Monasticon Hibernicum; Hall's Ireland.

PETER, Latinized Petrus Januus, is said to have been born in Forfarshire in Scotland, on 15th August, 1514. He studied at Geneva and Lausanne, and became intimate with Beza, to whom his uncle Henry Scirgerme made him known. Returning home in 1560, he was appointed co-tutor, along with Buchanan, of the young prince of Scotland, afterwards James I. of England. When the prince took the administration of the government, Young became a member of the privy council. In 1580 he was sent as ambassador to Frederic II. of Denmark, to conduct the negotiations as to the possession of the Oeste bay. He afterwards attended James on his romantic journey to Denmark to bring home his queen, and was employed in various missions to that and the neighbouring states. He ranks among the vindicators of Queen Mary. He prepared a short narrative of that queen's life and death, and its view of settling some of the charges expressed against her by David Chytraeus. This little work is incorporated with his Life by Smith. He settled in England, where he was knighted in 1614, and received a pension of 300l. In 1620 he retired to an estate which he possessed in South Wales, and engaged in the learned pursuits of life.

YOUNG, PATRICK. Latinized Patricius Junius, the son of Peter Young, was born on his father's estates in Ireland, in 1588, and was educated at Trinity College, Dublin, and at the University of Oxford, where he studied. Among his works are, as are afforded by contemporary continental critics, and the collection shows his circle of admirers has been both extensive and illustrous. From a young age he had been a admirer of the works of Greek and he carried on a considerable portion of his correspondence with his learned contemporaries in that tongue. His enthusiasm for ancient Greece extended to the modern inhabitants of that country, and he seems to have been anxious to reawaken the literature of their ancestors. He made the personal acquaintance of several Greeks, whom he invited to Ireland, supporting them there by his own funds, and dedicated to the cultivation of learning. He does not appear that more than one of these ever had by his subsequent exertions for the regeneration of his countrymen, the views of his enlightened patron; yet has not left behind him many literary remains of considerable value. He was an indolent man, and not anxious for literary fame. Seddon dedicates to him the 'Marmara Arundeliana,' a snarling term, describing himself, in drawing up the 15th as doing little more than collect and arrange the manuscripts which Young had, and the merit of which can only be assisted by his countryman, who translated the Latin works of King James. On the arrival in Ireland the Alexandrine MS. of the Bible in the royal library, which he had charge, he commenced a critical edition of some of the older MSS. of the whole contents of the MS. Of his exertions to be in pursuance of this project he left behind him a few vestiges. Among these there is a collection of MSS. from the fifteenth chapter of Numbers, which he published in the sixteenth volume of Polyglot Bible, under the title 'Patricii Junci Annotationes quas conven- em ad MS. Alexandrini Editionem, in quibus Colenso ex antiquissium eum Textu Hebraico et veterum Latinorum.' It was published in 1633, an edition of the Epistles of St. John, from the same MS., which will be found in the first volume of the 'Sacrosancta Concilia' of Labbe and Cossartina. In 1638 he published and dedicated an ' Annotationes in Revelationem,' written by his friend Robert Polio, bishop of London, in the time of Henry IV. It is said that he was the cause of applying the fees of the royal library to several other literary undertakings, and when the supremacy of the Parliamentary party suppose...
him of his appointment in that institution. In 1649 he retired to Bromfield in Essex, where he lived with his son-in-law Mr. Atwood. He died on the 7th September, 1652, according to a monumental inscription preserved in Bromfield church.

(Thomson, *Vita quarundam eruditorum et illustrarum tum Britannicarum.*)

YOUNG, EDMUND, was born in 1683, at Upham, a village about eight miles from the city of Winchester, in Hampshire. His father, the Rev. Edmund Young, was born in 1643, was educated at Winchester College, of which he was an independent member, October 13, 1705. A few months afterwards, on the death of the wife of his father, who was an annuitant, he removed to Upham, where he resided, he removed to Corpus Christi College in the University of Oxford, which was also one of his father's friends.

In 1708 he was nominated by Archbishop Tenison to a fellowship in All Souls' College, where he served two years afterwards as a tutor. He then, in 1710, was advanced to the degree of B.C.L. and to have adopted those religious principles which he retained throughout life. Tunstal, who frequently visited All Souls', speaking of him, says, 'The learned young Mr. Young has two last, on women, in 1727-8. They were extremely successful. Herbert Croft says that Young acquired 3000l. by them, but leaves it uncertain how the whole sum was obtained, by sitting, on the authority of Spence, that the Duke of Grafton gave him 2000l. for them. In 1728 he was admitted on Sir Robert Walpole being made a knight of the Garter.

In 1724 Young took orders, and was nominated one of the royal chaplains. He immediately withdrew his tragedy of 'The Brother' from the players, who bad it in rehearsal. In 1727 he published 'The Death of the Marquis of Carabyn,' in 1728, 'Ocean, an Ode, with a Discourse on Lyric Poetry,' to which was prefixed 'An Ode to the King, Pater Patriae,' and 'A True Discourse on the Book of Job,' and a poetical Letter to Mr. Tickell, occasioned by the Death of the Right Hon. Joseph Addison, folio.

Young had been tutor to Lord Burleigh, son of the Earl of Exeter, but having quarrelled with him, he went to New College, London, in 1710, so that he had been writing poetry for some years before he published any. On the 23rd of April, 1714, Young took the degree of B.C.L., and in the same year published a Poem on the Death of Queen Anne. He died in 1720, in consequence of his failing health as well as his poetry. For the foundation of the Codrington Library was laid, he was appointed to deliver the Latin oration, which he published, 'Oration habitia in Coll. Omnium Animarum curae, and his reputation as a bibliophile excelled Clucheot-Codringtonianae,' Oxon, 1716, 8vo.

On the 10th of June, 1719, he took the degree of D.C.L. In the same year his tragedy of 'Byssus' was acted at Drury-Lane with considerable success; and he published a 'Plea's criticism on Young's Works; and a poetical Letter to Mr. Tickell, occasioned by the Death of the Right Hon. Joseph Addison, folio.

1733, was under ten years of age when the first books of the 'Night Thoughts' were published, while Lorenzo is represented as having been married to a lady whose name in the poem is Charis, and who died in childhood, leaving a son, Florelo.

Young seems to have begun the 'Night Thoughts' soon after the death of his wife. They were published in London, 1742-4. In 1735 he brought out his tragedy of 'The Brothers,' and in 1728 published one of those 'hymns of which Society for the Propagation of the Gospel, but the play having been unsuccessful, he gave the Society 1000£.

His prose work, 'The Centaur, not Fabulous,' in Six Letters on the Subject of Religion, was published in 1728. There was also a letter from Secker to Young, dated July 8, 1729. Secker was then Archbishop of Canterbury, and Young, at that time 74 years of age, had been soliciting the archbishop to use his influence with the king to obtain some preference for him. Secker's letter is characteristic. He excuses himself by saying, 'No encouragement hath ever been given me to mention things of this nature to his majesty: and concludes by observing, 'Your fortune and your reputation set you above the need of advancement, and your sentiments above that consciousness, if you would destroy which, of that of the public, is sincerely felt by, &c.' Young would understand, if he did not feel, Secker's allusion to the inconsistency between his 'sentiments' and his solicitation for worldly advancement. 'The Last Days' of this publication were 'published in 1739. At Greenwich, on the 4th of January, 1781, his ruling passion received a slight gratification—he succeeded Dr. Stephen Hales as clerk of the closet to the Princess Dowager of Wales.'

Young's second son Frederic was educated at Winchester, whence he went to New College, Oxford, and then to Balliol College, from which, according to the 'Biographia Britannica,' he was expelled for misbehavior. According to the same authority, Young was so much incensed at his son's misconduct that he refused to see him, even on his death-bed, but left him the bulk of his fortune, which was considerable. He left 1000£. to his housekeeper, and added a sum, by which he contrasted that, if she destroyed his manuscripts after his death, 'which would greatly oblige her deceased friend.' He left another 1000£. 'to his friend Henry Stevens, a huther near the Temple Gate,' but Stevens died before him. Young's son erected a monument to his mother and to his son in Westminster Abbey, under the inscription:

Young, from the commencement of his career as a writer almost to the termination of his long life, displayed an eager desire for place and preferment, and seems never to have missed the opportunity of placing his courtiers, who had them at their disposal. Every work, whether in prose or verse, each separate satire of 'The Love of Fame,' and each separate book of the 'Night Thoughts,' was addressed to some person of distinction, including Queen Anne, George I., and George II., and generally in language of the most unscrupulous flattery. Place, after all, he never obtained, and, except the offices of royal chaplain and clerk of the closet, the only preferment which he ever reached was the rectory of Welwyn, and that was given him by his college of Christ Church. Young's private character has not been minutely described. Croft went to the residence of his housekeeper in order to obtain information from her, but she had died just before. After her marriage he lived much in retirement at Welwyn, 'the world forgot him, and enough to be almost by the world forgot.' He seems to have been visited by few, but Count Tschmer, a foreigner, who spent four days with him when he was very old, says that young's character was such that he would have been polite, and his conversation lively and entertaining. He was strict in the performance of his religious duties, domestic as well as public. His asceticism and meditation was among the tombs of his own churchyard, but he does not seem to have been a great lover of gardening; his parisioners were obliged to him for a bowling-green and an assembly-room.

The distinguishing characteristic of Young's intellect was the fertility of his fancy; but the imagery with which it was supplied and the manner in which that imagery combined, were such as to qualify him for a wit rather than for a poet. He has apparent no taste for the realities of external nature, but he has metaphors, similes, and laboured comparisons drawn from all kinds of sources in extraordinary abundance. The combinations are often original, often beautiful, sometimes brilliantly scented, but in no instance do they derive merit only from words, but are for illustration and unsuitable to the circumstances in which they are used or the effect which he intended to produce. This want of skill in the adaptation of meanings, and the propriety of the poem, is a marked defect of his poetical character. But he has another defect, which, though of much less consequence, would have disqualified him from ever becoming a great poet. His versification is that of a versifier, not of a poet; even in the adjustment of feet, but but of rhymes, of lines, and half lines, and almost utterly devoid of the melody of rhythm. His favourite form of language is tithes, which may be suitable enough for the wild, but is a little suited to the poet. It must be admitted however that his language is often very compressed, and his lines are frequently a pregnant brevity which gives point and force to his illustrations.

The 'Last Days' consists of a series of descriptions of the world, which has a tend to attention of the terrors of the wicked, and the nerves of the virtuous. Sublimity is generally aimed at, but rare is it ever achieved; there is much of violence and extravagance in a stead of it. The versification is elaborately correct, but not natural. It was published in 1788, and is a very poor work. 'The Force of Religion' is a poetical dialogue between Lord Guildford and Lady Jane Grey previous to her execution. The pathetic is evident in it, as they are by Young, instead of being a no doubt he intended, specimens of magnificent imagery are extravagant to a degree of absurdity which is absurd and, but Young's peculiar style and the condemnation of these sketches, often slight and generally superficial, is true, and spirited, and sparkling with illustrative truth; and though much of the manner in which they described passed away, they are still perfectly intelligible and amusing. In poems of this kind, even Young's peculiar taste for antithesis, and his short and broken style of versification, can hardly be regarded as objectionable. The 'Night Thoughts' are a series of argumentative poems in blank verse, in proof of the immortality of the soul and of the existence of God. The necessity of religious and moral conduct, Young's exhibitions of life are those of a man who had dwelt with the world, and had observed it well; and though they are generally somewhat gloomy, and often a tragedy, yet they are not without their bright spots. The whole is a beautiful poem, written in the style of blank verse; and it is of those poems which will be read for the sake of their beauty, and not for the sake of their argument or narrative. The 'Love of Fame' is a series of satires, each more or less amusing. In poems of this kind, even Young's peculiar taste for antithesis, and his short and broken style of versification, can hardly be regarded as objectionable.
abundance, superabundance we may say, of its illustrative ornaments. We have already described the nature of these ornaments in speaking of his poetry generally, but an instance or two may be given just to show his mode of working them. Thus Narcissus is compared to a dew-drop—

So bright, so beautiful, so pure;
Sparkling, and exalted, and gone to heaven.

The disappointment of human hopes—

Life to the last, but heaven's alone.

Sense and wit compared—

Sense is our beacon, wit is but the plaque;
The road is the same, the manner differs.
Sense is the diamond, wealthly, sad, sound;
When one of the image—But wit, apart is a diamond still.

The advantages of conversation—

Thoughts shut up wait air.
And spoil like fruits until they are expunged.

The Centaur not Fabulous is a satire in prose, an exaggerated display of the life "in vogue," as he expresses it. The Remarks on Original Composition were addressed in a letter to Richardson the novelist, and though written when Young was very old, they are not only of good sense but great sense as much as if they had been written ir the prime of life; they are rather gloomy perhaps, but very entertaining.

Young wrote several Odes, some expressly in imitation of Fidlar's manner. They are all signal failures. He has little or no poetical imaginations, probably as inapposite to the dignity of the ode, and he has nothing in the place of them. The thoughts are either common or bombastic, and the versification is only fit for nursery rhymes. The Centaur is a collection of several of these verses written in a familiar style, and though imbued in tone, indicates no decay of his powers.

The three tragedies are all of the heroic class. The characters are above nature or out of it, and their thoughts and hasty and unprepared to ordinary humanity; he wrote no sympathy. The Revenge however still keeps possession of the stage whenever an actor appears who is capable of displaying the exaggerated but magnificent passion of Zangis. The plot is an imitation of that of Othello; it has more incident than either of the other tragedies, and the thoughts and language are nearer to those of actual life.

(Coote's 'Life of Young,' in Johnson's Lives of the Poets. Bioggraphia Britannica; Young's Works.)

YOU SK. A. B. H. With men fates as much as if they had been written in the prime of life; they are rather gloomy perhaps, but very entertaining.

Arthur Young was a Doctor of Divinity, a prebendary of Canterbury, and chaplain to the Lord of the Manor of Compton. The subject of this memoir was his third son.

Arthur Young was educated at Laetam school, where he went in 1778, being then about seven years of age. Leaving that school in 1781, he showed considerable talents at school, where he remained till 1786, when he was apprenticed to the mercantile house of Mr. Robinson, at Lynn. In the hopes of his becoming in time a thriving merchant; he had no need to this profession; but as this apprenticeship cost, would have maintained him at college, and he might have become qualified to hold the rectory of Bradford, which was then held by his father. As the rector of a large agricultural parish, there is every reason to suppose that his latent love of agriculture would have been fostered. He would probably have been equally zealous in this pursuit without so great a power to merit success as he was called on by circumstances to make the improvement of the several farms he occupied.

Having no taste for business, he took to reading at Lynn, and read every book he could procure. At seventeen years of age, he was much attached to political pamphlets, entitled 'The Theatre of the present War in North America,' for which he got 10l. worth of books from the publisher, to a him a great treasure. After his father's death, which happened in 1790, he was much tempted, by the offer of a pair of elections, to enter this world without, but his mother would not hear of it, and like a good son he gave up all thoughts of it. He began a periodical work, called the 'Universal Museum,' but gave it up after the sixth number, by the advice of Dr. Samuel Johnson. His whole fortune then consisted of a copyhold estate of 20 acres, worth annually as many pounds. His mother had a lease of a farm of 50 acres at Bradfield; and on the renewing the lease, she gave him the management, and he commenced practical farmer, without any real practical knowledge of farming, and was full of wild schemes. He afterwards himself confessed. In the following year he became a contributor to the 'Universal Museum,' the first agricultural work he tried his pen in. He married in the same year, 1783, Miss Mary Wilmot, as a marriage of convenience on both sides, this union was not very happy. In 1797 he undertook the management, on his own account, of a farm called Sampford Hall, in Essex, consisting of 300 acres of land. There he was in his element, making experiments and observing, and it is when he published the results in two thick vols. 4to., under the title of 'A Course of Experimental Agriculture, containing an exact Register of the business transacted during five years on near 300 acres of various soils. Dodsley, 1797. This style in which he brought out his book, which means instructive, was brought out, on fine paper, large type, and wide margin, proves that either the public were beginning to have a taste for agricultural works, or that Arthur Young had too favourable an opinion of the use of his book, which was injured by the publication, and who bore it, it is not now easy to say; we only know that we bought the book handsomely bound in call at the price of waste paper. But this work was published after his tour through the Southern Counties of England, a work which became very popular, and of which several editions were sold. Young was a keen observer, and had a ready and lively mode of communicating his observations; if he was sometimes rather hasty in his conclusions, or supercilious in his remarks, he succeeded in elevating them by an easy and sometimes imaginative style. An account of proceedings and experiments on a poor farm, not always very judiciously planned or executed, could not be very entertaining or instructive. After five years, in which he suffered great losses and disappointment, he was glad to give 100l. to a practical farmer to take the lease off his hands. Where the literary and scientific farmer had failed entirely, the practical farmer saved a little fortune. It is amusing to read Young's invective against the soil, climate, and everything about this horrid farm: but when it is considered that he only saw it from Saturday till Monday, and was occupied as a parliamentary reporter the remainder of the time, the wonder is, the sense of this will be caused by the fact of his having time to note down the results of his experiments so as to make them true. In the year 1794 he was induced, by the promise of his 'Six Weeks' Tour,' to take another in the north of England, of which he published a narrative and the results of his observations; but this enterprise, like all his others, was in vain, and the wonder is, the sense of this will be caused by the fact of his having time to note down the results of his experiments so as to make them true.
gave it a strong impetus, and blew it into a vivid flame. Many tours had been made through every part of Britain, and many lively descriptions had been published, but in none were the agricultural and political circumstances of different districts accurately recorded. Wherever he went he was received by proprietors and farmers with the greatest frankness and hospitality. In his discussions on their different modes of cultivating the soil, he acquired extensive practical knowledge, and also imparted it to his hosts: by placing before them the more rational and economical courses adopted in other districts, he led them to make experiments; and if these, somewhat hastily conducted, often proved failures, he always tended to make men reflect and compare, and often led them to see their errors in management. By means of his publications distant parts of the country became acquainted with practices which were entirely unknown before, by a small circle in which they had been gradually adopted. Even the failures, occasioned by adopting systems and rotations not suited to every soil, gave useful lessons, and pointed out the principles on which the most advantageous systems were to be founded.

Wherever Young met with the cultivation of any peculiar plant, whether for the use of man or beast, and observed more than ordinary luxuriance in its growth, he became an enthusiastic admirer of it, and recommended it for trial to his husbandmen. Of these introductions he was justly a public virtuote, and he recommended its cultivation on every opportunity. Another plant which gave an attention was wild chicory (chicorium intybus), the feeding qualities of which he much exaggerated, thinking it so important, that in the greater part of England it was established as a necessary article of diet.

Mr. Young was also secretary, in order to ascertain the state of agriculture in all parts of the kingdom, one of the questions was, "Do you sow chicory?" whereas this plant had only been tried by a few individuals, and not lost its momentary novelty on that account. We mention this circumstance to show how warmly he took up any apparent improvement and endeavoured to promote its general adoption. This zeal in the cause gave a charm to his works, which were written in a lively and imaginative style, to a subject where nothing was met with but dry details. When he sometimes led his readers a little out of the straight path of sober practice, they readily forgave him for the sake of his motives and his zeal. In 1771 he published that useful and well-known work entitled the "Pamphlet of the Farmer's Calendar," which has gone through innumerable editions, and is still a standard agricultural work. At the same time, as if to show the versatility of his genius, he published "Political Essays on the present State of the British Empire," and "Observations on the General Course of Weather." In 1773 he published a pamphlet entitled "The Land," in which he endeavoured to increase his income, which, notwithstanding the profits of his publications, did not suffice for his expenses and experiments, he had become a parliamentary reporter for the "Morning Post," in which an arduous task he engaged for five years, which brought him no approach to the detriment of his farming operations, which he could only occasionally superintend.

In 1774 he published "Political Arithmetic," which work was soon translated into several foreign languages. In 1776 and 1777 he made his tour through Ireland, one of those which greatly increased his knowledge, if not of the perfections of farming, certainly of its most glaring defects in that fertile country. His decided disapprobation of the bounds of the power of the clergy, and the disadvantages of the land-captain, who on the land-captains of corn to Dublin drew the serious attention of the ruling powers to this subject. In the next session of parliament this bounty was reduced one-half, and soon after entirely abolished. For this essential service to the prosperity of Ireland, he received only the cold thanks of the Dublin Society. He warmly supported the claims of the Roman Catholics to the removal of all political disability owing to difference of religion, showing that the penal laws then in force were laws against the industry of the country.

In 1777 Mr. Young received a medal from the Salford Agricultural Society, inscribed "For his Services to the Public." After this he undertook the management of the estates of Sir Richard Gregorian at Milltown, in the county of Cork, where he resided for two years in a house built on purpose for him. In 1779 he returned to his mother at Bradford; it was then that he had the project of emigrating to America, which he relinquished in consequence of the objections of his mother. He therefore bid himself with renewed zeal to the practice of husbandry. He was employed with his own hands in various scientific pursuits, analyzing soils, and making numerous experiments, for which he obtained the gold medal of the Society of Arts. In 1782 he entered into a great controversy with Mr. Capel Loft on the expedients of the county of Suffolk presenting the government with a 74-gun ship. This was carried on some time in the "Plymouth Post," and drew the attention of the public to that paper.

The fame of Arthur Young had now spread far and wide, and reached even the frozen regions of the North. The Emperor of Russia was informed that the English agriculturist could be instructed by him in agriculture, and in the following year sent him a magnificent golden snuff-box, and two warm white mink coats for his wife and daughter.

In 1784 he began the publication of his "Anatomy of Agriculture," which he continued till the work extended to 45 vols. 8vo, containing a great fund of agricultural information. In this work all the contributions have been of their authors annexed, which adds much to its advantage, even King George IV andyoung Mr. Young an account of the farm of Mr. Ducket, at Petersham, under the signature of Ralph Reuben. Among other important communications may be noticed the "Letters on the present State of Agriculture in Ireland," written by Dr. Banks, and his "Outline of a Professor of modern history at the university of Cambridge.

In 1785 Mr. Young's mother died; he always entertained the warmest affection for her, and in several instances we have seen, gave up favourable schemes in deference to her wishes. In the next year he lost his respected son, who was killed by a fall from his horse while hunting near George III.

In the spring of 1787 he received a pressing invitation to visit France, to accompany the Chevalier de Broglie to the Pyrenees, which he accepted with joy, and returned to England in the following winter. At this time a discussion took place about the Wool Bill, and the farmers of Suffolk deputed Mr. Young to support a petition against it, and the land-banks, which was deputed from Lincolnshire for the same purpose. They did not however meet with complete success, but they caused some of the most obvious clauses of the bill to be modified. The manufacturers, for his interference, were sufficiently rewarded.

In 1789 he began to circulate his "Agricultural Survey of that country, which the French agriculture acknowledged necessary to have one edition of his "Agricultural Survey of that country, which the French agriculture acknowledged necessary to have one edition of their systems of husbandry. He did not however publish it till he had made a third tour through that extensive kingdom. During the interval of the two last tours he was occupied in introducing the collecting of grass seeds by hand, for the purpose of destroying artificial meadows, and, among many other useful grasses, introduced the cockedfoot (dactylus glomeratus) and the created grass (cyonurus cristatus). The style of his books is lively, and his descriptions amusing as well as interesting.

About this time he entered into a correspondence with General Washington, which was afterwards published in a pamphlet. Another circumstance on which he was very proud was that he had been commissioned by the king of a Merino ram. In 1788 he published a pamphlet, which met with great success, entitled "The Example of France a Warning to Britain." He received the thanks of several patriotic associations, while the Tory party celebrated him of apostacy, and he had been rather inclined to favour the liberal party and approve of the French revolution, but the horrors which it brought forth entirely disgusted him. In this pamphlet Mr. Young took occasion to show how the Jacobins, those infamous villains, who had established under the name of the Jacobinical wav, and a which lie himself served as a private in the ranks, under Lord Brougham, afterwards Marquis Cornwallis.

In order to put into practice his various schemes for the
improvement of waste lands, he purchased 4400 acres of uncultivated land in Yorkshire; but luckily for his purse, he would probably have suffered much in the experi-
ment, the Board of Agriculture was established, and the
office of secretary was offered to him. This was exactly
suitable to his taste and activity, and the salary of 400£. per
annum, with a house rent-free, made the situation desirable
in the score of industries.

A great compliment was paid to Arthur Young, in 1801,
by the French Directory, who ordered all his agricultural
works to be translated and published at Paris, in 20 vols.
and, under the title of "Le Cultivateur Anglais," and in the
same year, he had described Litchen, Norfolk, Hart-
ford, Essex, and Oxford. In 1795 he published two poli-
tical pamphlets, entitled 'The Constitution safe without
Reform,' and 'An Idea of the present State of France.'

At the desire of the Board of Agriculture he drew up
the Country Reports, beginning with that of Suffol, to
which he added four others in second Lithograph, Nov.
and Oxford. In 1798 he published a letter to Mr. Wilberforce,
"On the State of the Public Mind," and, in 1800, a pamphlet
"On the Question of Scarcity." In 1804 the Bath and
Wells of England Society adjudged their Bedfordford medal
to him on account of a pamphlet on the "Foundations of
Manners." In the same year he received the present of a
snuff-box from Count Rostopchin, governor of Moscow,
which was turned by himself out of a block of oak, and
which he preferred to all the snuff-motives in Russian,
"From a Papal to his Master." Over the motto were three
erculosis in burnished gold, forming the cipher A. Y.

In 1803, at the request of the Russian Ambassador, Mr.
Young sent his son to Russia, to make a survey of the
crimea, and to teach the Russian language. He was
liberally remunerated; and with the same he re-
cieved he purchased an estate of 10,000 acres of very rich
land in the Crimea, and settled there.

In 1806 Mr. Young received a gold medal from the
Academy of Arts, for his "Agriculture for long Mr. Young's mind. He
began to turn his attention to religious subjects, which in
the battle of his secular occupations had not occupied
much of his thoughts before. He began now to read and
examine, and to satisfy himself as to the most important
texts of the Evangelical, with a view of enabling himself

antient Gaelic poems. An interesting paper by Dr. Young on the 'Origin and Theory of the Gothic Arch' is published in the third volume. In this paper the writer offers an opinion that the Gothic arches were invented to employ pointed arches in their buildings from the knowledge of their mathematical properties: from an investigation of their strength, on scientific principles, he comes to the conclusion that a pointed arch whose radius of curvature is equal to half the span, or the distance between the supporting pillars, is the weakest of the kind, and also that the strength increases as the radius of the curve becomes, within certain limits, either less or greater than the span. In comparing low Gothic arches with arches of a semicircular form, he proves that, when the radius of the latter is equal to three-fourths of the span, the strength is to that of a semicircular arch of equal span as 1000 to 1257; and when the radius is two-thirds of the span, as 1000 to 1210. In the fourth volume of the 'Transactions' there is a copy of Dr. Young's paper on the correction of the spheroidal aberration in the object-lenses of telescopes.

Besides these contributions to the Academy, Dr. Young published separately. An Essay on the Phenomena of Sound was published in 1775. (The paper was not read in the Academy.) He subsequently published a short essay on the primitive colours in solar light, and on the precision of the equinoxes. His last work was that which he entitled 'Principles of Natural Philosophy,' 1802, 1803, and which contains a restatement of the features of the physics which he had delivered at the University.

YOUNG, THOMAS. There are no trustworthy materials for the life of Dr. Young, and for some years past it has been known that a biography of him is in preparation by an author who has been specifically qualified for the undertaking. With much regret at not being able to wait the appearance of this account, we must do the best we can with what is contained in the Gentleman's Magazine' and the Essay on Philosophical Language, which he wrote.

Dr. Young was born at Merton in Sussex, on June 13, 1732: his parents were of the Quaker persuasion. He received his first education at a dame-school at Minahead, where he resided with his mother's father, Mr. Robert Davies. It is said that he could read tolerably at the age of six years, and his early memory was extraordinary. As six he was placed with a schoolmaster at Bristol, and, two years afterwards, the access which he gained to the instruments of a surveyor of his acquaintance seems to have decided his vocation: he applied himself immediately to mathematics. From all this he was removed to Cambridge. He would have done well to have taken their advice: the great drawback upon his scientific hopes was the want of a sufficient knowledge of mathematics, which all who can appreciate the truly scientific spirit of the age got on with but little knowledge of, and the presumption is strong that if he had been able to give full vent to his talents with regard to that subject, he would have done more than his share to elevate the sciences, and the position of his country in the world of science.

M. Arago says that during this period he learned, besides Greek and Latin, also French, Italian, Hebrew, Persian, and Arabic, the two former of the last five to find out the contents of some books of Euclid, Archimedes, and Homer, the very books known to us in manuscript. He never learned the Bible in the original, the two last to decide for himself a question raised in casual conversation as to whether the Oriental languages presented differences as decided as the European. Young's early acquirements are known to have been extensive, and a very fair talent for languages, but it is hardly safe to attribute his learning any one particular language to a conversation which probably, if it ever happened at all, was the consequence of his thoughts dwelling on the subject, and not the result of study.

Moreover, it is to be remembered that the friends and relatives of a boy of talent are very apt to exaggerate his early acquirements, particularly if he afterwards becomes a distinguished man.

At all events he was also much given to botany, and determined to make himself a microscope for the examination of plants. The algebraical formulae which he met with had fluxional symbols, which arrested his progress; he accordingly set himself to study fluxions, that he might get the knowledge necessary to understand and construct a microscope to go on with his botanical pursuits. His close attention to these and other things had nearly proved fatal to him at the age of fourteen; symptoms of consumption appeared, which however were happily overcome by early attention.

Among the English, says M. Arago, it is rarely that a man of fortune, when he takes a private tutor for his children, omits to find him a camarade d'étude some youth of an age who is particularly successful in his studies. They were not, we confess, aware of this nearly universal custom. Moreover, Dr. Young had been admitted to the society of a gentleman of Herefordshire, as companion to his own private tutor of both was Mr. John Hodgkin, afterwards published the 'Calligraphia Graeca'.

To Young himself was attributed the suggestion of the word 'calligraphia' to be written by him in a note in the margin of his writing book in 1773, which he may not have been the first to use, but he was the first to introduce its use. On the day of Young's arrival at his destination his tutor desired to copy some sentences as a specimen of his handwriting; he had made a point of not turning his back on the test, he begged to retire into another room. The fear of his absence excited some remark; but on his return he presented the sentences required, not only beautifully written, but translated into nine different languages.

At this time he drew up a synopsis of the development of philosophical systems of the Greeks, from the original subtilities, according to his friends. M. Arago speaks of writing as still in existence, and states that doing preparation Young's mind was gradually prepared to absorb another of the peculiar principles of the system, which he was brought up with, which took place some years afterwards. During journeys to London, also made for this time with the family in which he lived, Young became acquainted with, and was taught chemistry by, Dr. Hogg, of the Royal Institution. It is a moment to advocate the claims of Dr. Hogg as a material portion of the discovery of the atomic theory as the place of the allusion seems unfortunate; for the presumption is strong that if he had been able to give full vent to his talents with regard to that subject, he would have done more than his share to elevate the sciences, and the position of his country in the world of science.

His maternal uncle, Dr. Brockleby, now presented to Burke, Wymsham, and the Duke of Richmond, both latter, then Master of the Ordnance, offered the position of assistant-secretary: this he was prepared to accept, and he left Cambridge. He would have done well to have taken their advice: the great drawback upon his scientific hopes was the want of a sufficient knowledge of mathematics, which all who can appreciate the truly scientific spirit of the age got on with but little knowledge of, and the presumption is strong that if he had been able to give full vent to his talents with regard to that subject, he would have done more than his share to elevate the sciences, and the position of his country in the world of science.

All who can appreciate the truly scientific spirit of the age got on with but little knowledge of, and the presumption is strong that if he had been able to give full vent to his talents with regard to that subject, he would have done more than his share to elevate the sciences, and the position of his country in the world of science.

As soon as Young had received his doctor's degree, he settled in London as a physician, and continued to practice till his death, which took place May 10, 1829. The authorities here begin to cease giving dates, and no plant appears to have been raised to a prominent circumstance of his remaining life in order.

As a professional man, Young was not successful. Knowledge, and his power of tracing consequences to him, it is said, an undiscouraged and warning practice. He had a keen perception that the just as well as to be approved. It is hardly necessary to point out that which are connected with medicine like to hear, and his courses were accordingly not well attended: indeed it has been said that they were above the students' comprehension. As a lecturer at the Royal Institution, it is said that he was much in demand between audiences. With the effect of these and other disappointments was combined the feeling that his pure and successes were not properly appreciated, and that a long time was not the case. On these points he is said to be very well to support the comment currently made by M. Arago.

In 1818 Young was appointed secretary of the Royal Society, and in 1821 he was elected a member of the British Association for the Advancement of Science.

M. Arago makes some strong remarks upon his original not having been inserted in Westminster Abbey, and says that there was no occasion for such an omission.
YPR, 719

YRIARTE, JUAN DE, was born at Orotava, in the island of Tenerife, on the 15th of December, 1702. His father was a native of Orotava, and his mother was a native of Tenerife. His father, who entered a high opinion of Frenchmen, sent him to France, under the charge of Pedro de Hely, French consul in the Canaries, who was returning to his native country. He sailed from Cadiz on the 10th of December, 1718, and arrived in the Canaries 1724. The year 1714 was spent in attendance at the public schools of Paris; in April, 1715, Hely transferred his residence to Rouen, whither his ward accompanied him. At what time Yriarte returned to Paris is unknown, but he spent eight years in the college of Louis le Grand, where he distinguished himself by his acquirements in the classical languages and in the mathematics. Before returning to Tenerife he visited London, apparently with a view to make himself master of the English language. His stay there was short: the intelligence of his father's declining health precipitated his departure.

On his arrival at Orotava, some time in 1724, he found his father already dead. He fulfilled his father's wish that Juan should proceed from the college of Louis le Grand to the University of Salamanca, and study law in some of the Spanish universities. The young man remained some months at Orotava, seemingly insolvent to follow out the career designed for him by his father. He went to the University of Salamanca, and there he was busy extending his knowledge of the English language acquired during his short residence in London. At last he resolved to comply with the wishes of his deceased parent, and sailed for Spain about the end of 1726.

Yriarte's knowledge of languages and his passionate love of books alike qualified him for filling the latter post. During the thirty-nine years that he continued librarian he added two thousand manuscripts and upwards of ten thousand printed volumes to the collection. In 1729 he published a catalogue of the logical works contained in the library; in 1735, a catalogue of the mathematical works. In 1739 he published the first volume of a catalogue of the Greek MSS., in the royal library, illustrated with notes, indexes, and apparatus. A second volume was promised, but it never appeared.

The linguistic attainments of the librarian were frequently put in request by the government officials, and so valuable were they found, that on the 21st of February, 1740, he was appointed official librarian to the city of Tenerife, and, forty years later, to the city of Santa Cruz. The secretory observed in a ministerial cabinet renders it impossible to learn with certainty the exact qualifications he showed himself to be possessed of for this office; but in the whole twenty-nine years that he continued to fill it, he enjoyed a high reputation among Spanish statesmen for method, punctuality, and severity of integrity.

The laborious duties of the librarian and official processing of materials, which represents the Fall of Man. It is a very old picture, and attributed to Van Eyck, but this seems doubtful. A flat stone in the cathedral covers the grave of Cornelius Jansen, founder of the sect of the Jansenists, who was bishop of Ypres in 1665.

Hassel, Handbuch; Handbook of Holland, Belgium, etc.; Stein, Geography, Lexicon.)

The general public hardly knew, the time how distinguished a benefactor of human knowledge was thus treated: it is now only to be wished that at least the course he took has been as defensible as the steps of others. As the time went on, his paintings and those of his daughter were as little known as they were. It is to be hoped that the examination of his remains will be made without delay, as it is frequently found that his hints are far from being exhausted. The points which should be most prominent in a general recapitulation, are the amount and nature of his works, the class of his publications, and their value. The views are now generally adopted, and been much enlarged.

Young's writings are numerous, and we have no means of ascertaining their number, and during the first forty years which he devoted to this purpose, the labours of his life were not without profit. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world. He was a man of great scientific acquirements, and had acquired a knowledge of the principal languages of the world.
later did not occupy the whole time of Yriarte. In 1743 he was elected a member of the Royal Academy, and continued till his death to take an active part in its labours. The chief labour of devising an improved system of orthography, punctuation, and accentuation for the Spanish language fell upon Yriarte: he was ordered by the king to compile a Spanish Latin Dictionary, in which however he proceeded no further than the letter A; and he published a Latin grammar in Castilian verse. He had also a hand in revising and improving the "Hispania Nova" of Nicolas Antonio, and the "Biblioteca Arabica-Hispana Escrita" of Oviedo, and composed for the Royal Academy, or for the translation of Martial's, and of occasional verses both in Latin and Spanish, was published by subscription after his death.

Juan Yriarte died at Madrid, on the 23rd of August, 1771, in the sixty-ninth year of his age. In addition to the works already mentioned, he left in MS. "Historia de las Islas de Canarias," and "Palografia Griega." He also contributed largely to the "Diario de los Literatos de España." Three brothers of the name of Yriarte, nephews of Don Juan, had distinguished themselves in the public service, and in the literature of their country, but the materials for their biography are very scanty. We have been unable to ascertain even the baptismal name of their father, but as they appear to have been all born in Teneriffe, it is probable that their parents were natives of that island, as the prosperous fortunes of Juan de Yriarte induced his nephews to try their fortune in the mother-country.

Bernardo, the eldest, appears to have been born about 1702. He was a member of the Council of State, and of the Council of the Indies, and was created a knight of the order of Charles III. He was a member of the Royal Academy of St. Ferdinand, and nominated its patron by Charles IV. in March, 1792. When the French took Madrid, in 1808, Bernardo Yriarte was appointed a Councillor of State by Joseph Bonaparte. On the return of Ferdinand VII., Yriarte fled to France, and died at Bordeaux, on the 11th of July, 1814.

Domingo, the second brother, was born in 1746, and entered the diplomatic service at an early age. When he had a prolonged residence, first at Vienna, and then at Paris, as secretary to the embassy and chargé d'affaires, he was sent as minister plenipotentiary to the king and republic of Poland. On the 22nd of July, 1795, he signed, along with the French ministers, and the Peace of the year II., he became king of Spain and the French republic. Returning thence to Spain in bad health, he died at Girona, on the 22nd of November of the same year. Just before he had been appointed ambassador to France.

Tomás, the youngest, but most distinguished of the brothers, was born about 1750. Under the direction of his uncle Jean he made rapid progress in the antient and modern languages, and was appointed chief archivist in the office of the principal secretary of state. This appointment left him ample leisure for literary pursuits, and the approbation which his first essays met with procured for him the editorship of the "Madrid Mercuryo." This journal, which was previously little more than a translation of the same name," became in his hands a useful and amusing publication.

In 1769 a new theatre was opened in Madrid; and in the course of that and the three succeeding years a number of translations from the French drama by Yriarte were performed on its boards. In 1778 an original comedy by Yriarte, "El Señorito mimado," (The Spoiled Child), was favourably received by the Madrid public. In 1779 a poem in five books, entitled "Los Poetas," and one in hexameters of Yriarte: it was upon this work and his fables that his reputation is most likely to rest. "La Musica" has run through five editions, and has been translated into most European languages. In 1781 he was a competitor for the prize awarded to the best work of the Spanish Academy, but the poem on June Melenz Valdez was preferred. Yriarte vented his spleen in a severe criticism of his rival's work in the "Mercuryo." "Fabulas Literarias" was published in 1792. Of these fables Foster remarks that their style is pure, and their versification elegant, and that they are characterised by a graceful naiveté that reminds the reader of Fontene, but without conveying any suspicion of imitation. In addition to these works Yriarte published epistles in verse, notes, critical miscellanies, a translation in verse of the four first books of the "Aeneid," and of Homer's "Iliad" and "Odyssey." He published a collection of his works in 1785, and an enlarged edition. His taste for French literature, or some other cause, occasioned suspension of his orthodoxy; in 1786 he was subjected to an examination by the Inquisition, and his replies were so little satisfactory, that he was laid under a close arrest until the trial. Finally, after 26 years of imprisonment, he was tried, and found guilty of high treason, and sentenced to death. He did, however, survive: he was attacked by epilepsy, and died of an inflammatory attack in 1809 or 1811.

Avenzoar, a Yriarte, who was born in Biscay, in 1635, and who died at Seville in 1658, was considered the best landscape-painter of his age.

Francisco Diego de Ainsay Yriarte, a native of Huesca, published, in 1712, "Translation of the Kings of Canaria, San Gregorio, Obispo de Aux," and in 1716, "Pinsei Yriarte, Grandes, &c., de la antiquissima Oda de Huesca." Antonio mentions that he was master of the grammar-school of Huesca, and died young, but without mentioning the year of his death.

Ainsay de la Vida y Labor de Don Juan y Yriarte prefixed to the collection of his works published in Madrid in 1774; the "Prefaces to the Collected Works of Tomas de Yriarte" published at Madrid in 1787; and the "Bibliotheca Hispanica Mexicana," by Pigon, published in 1819, and in the notice of the Life of Tomas de Yriarte, in the "Biografias Literarias," neither of which we have seen.

YRIEIX, St. [Vienna, Hauke.]
YRIEIX, Count [Hauke.]
YSTAD, [Sweden.]
YTTRIA. [Ytrrium.]
Ytttrium, a peculiar metal discovered in the earth's crust in the E style. The ore, which is found in Sweden, was first called ytterby, and afterwards soldilone, by name it is now generally known. The metal was separated by Wohler from the oxide, by first reducing it to the metal, and then decomposing it into water and yttric oxide. The oxide is a small brilliant scale, having a perfect metallic lustre; it is a bright blackish powder, composed of small metallic scales. This oxide has a great affinity for oxygen; it is red in colour, and its composition is yttric oxide, and oxygen, as the air, takes fire, burns with much splendour, and is converted into yttria. Yttria dissolves in dilute nitric acid, with the evolution of hydrogen; when immersed in a solution of potash, it decomposes water, and emits oxygen gas, without rapidity.

We shall now briefly describe the minerals which contain yttrium, or rather its oxide, yttria.

Gadolinite.—Occurs crystalline and massive. Forms an oblique rhombic prism. Cleavage imperfect, with a distinct fracture, and a conchoidal, sometimes splintery. Hardness 6 to 7; colour greenish black, very dark. Streak greenish grey. Lustre vitreous, inclining to resinous.Opaque, transparent on the edges. Specific gravity 4-238.

Mineralogy....

Yttro-

Mallorca. [Ytrrium.]

Before the blowpipe it decomposes, if not heated, and does not melt except in small splinters. When heated with precaution on charcoal, it incandescence and gives off the oxide of yttrium. It is used in medicine for its nitric acid, and in gelatinising.

Gadolinite is found at Ytterby near Stockholm, and at other places in Sweden, and also in Greenland.

This mineral has been repeatedly analyzed, and was somewhat various, according to the process employed by Berg, Klápströ, and Vanquelin, without the detection of the oxide of cerium, which was found by Bertelius, who gave the following as the composition of the mineral from Brolsdo—Silica, 24-10; Yttria, 45-33; oxide of cerium, 16-90; oxide of iron, 11-94; muriatic acid, 9-80.
In a specimen from Karasjok, Berzelius found 2 per cent. of glucina, and rather more than 3 per cent. of lime. The following analyses, by (1) Mr. Connolly, (2) Des-Thomson and Steele, (3) Mr. Richardson, exhibit a much larger proportion of glucina than that obtained by Berzelius:—

Scheerer has more lately detected 475 per cent. of oxide of lanthanum in the gadolinite from Hitteron.

Columbite of Ytttria, &c. [Fergusonite.]

Titanate of Ytttria, &c. [Polygonite.]

Yttriochromite:—No trace of crystallization. It is found between felspar and the state of lamellae, sometimes in grains not exceeding the size of a pepper corn. The longitudinal fracture of the lamellae is foliated, the cross-fracture fine-grained, the surface vitreous in the fracture. Colour yellowish brown, accidentally with green spots or stripes. Streak white. Opalescence. Scratches glass with difficulty, but is very distinctly scratched by it. Specific gravity 4-387. The pale yellow color is characteristic of Yttrochromite.

Yttriochromite occurs with the preceding, commonly in thin laminae, schist in grains. Fracture conchoidal in one direction, fine-grained in another. Lustre intermediate between vitreous and resinous; Colour brownish black. Streak white. Very small fragments are translucent, almost colourless, sometimes a little yellowish. Hardness equal to that of the preceding.

Analysis of the above by Berzelius:—

Before the blow-pipe they are all insufiable per se, but decrapturate and acquire a lighter colour. They are not acted upon by acids.

The above minerals all occur at Ytterby, and in the neighbourhood of Fahlum in Sweden.

P. C., No. 1770.

Having described the properties of yttrium and the minerals from which it is obtained, we shall briefly state the nature of some of the compounds.

Oxide of Ytttrium; Ytttria.—This compound, usually placed among the earths, is the only known compound of the elements of which it consists; and it exists as such combined with other earths and acids in the minerals above described. The properties of yttria,—that it is colourless, insipid, insoluble in water, and insufiable;—it is heavier than barytes, its specific gravity being 4-842;—it is perfectly insoluble in the caustic alkalis, but the alkaline carbonates, and especially carbonate of ammonia, dissolve it, and it is precipitated in solution by the ferric hydroxide of potassium. It has no action on vegetable colours.

It appears to consist of—

One equivalent of oxygen | 8
One equivalent of yttrium | 32

Equivalent | 40

It is the only oxide of yttrium known.

Chloride of Ytttrium is obtained by passing dry chlorine gas over a mixture of yttria and charcoal, heated to reduce the metal. It has the form of white brilliant needles, which easily melt into a crystalline mass. It is white, dissolves in water with the extraction of much heat, and speedily dissolves in the air. When yttrium is heated in chlorine gas, it burns, and the result is also chloride of yttrium.

Sulphate of Ytttrium is formed when the metal is heated in the vapour of sulphur; the resulting compound is of a grey colour, and is insoluble in water, but is decomposed by acids with the evolution of sulphured hydrogen gas.

Phosphuret of Ytttrium is obtained when the metal is heated in the vapour of phosphorus; combustion ensues, and the compound formed is of a greyish black colour, which, when put into water, gives out phosphuretted hydrogen gas.

Yttria and Acids combine to form salts of yttria.

Sulphate of Ytttria crystallizes readily. The crystals are colourless; they dissolve with remarkable slowness in water, which is however capable of taking up about 1-50th of its weight. When strongly heated, sulphate of yttria is decomposed, the whole of the acid being expelled.

Nitrate of Ytttria is obtained by the spontaneous evaporation of a solution of the salt; the crystals are colourless and extremely deliquescent.

Carbonate of Ytttria is a white flocculent precipitate, which is slightly soluble in the containing carbonic acid.

The properties of the salts of yttria are,—that their taste is astrangent and sweet; their density is greater than that of most earthy salts, and, unlike most salts of this kind, they are precipitated by ferric nitrates and potash, and potash produces white precipitates in them, which an excess does not redissolve; but the carbonated alkalies, and especially that of ammonia, redissolve the precipitate at first formed, when added in considerable excess.

The peninsula of Yucatan is surrounded on the west and north by the Gulf of Mexico, and on the east by that portion of the Caribbean Sea which is known by the name of the Gulf of Honduras. The republic of Yucatan borders on the south-east on the English settlement of Honduras and Balize, but the boundary-line between them has never been defined, nor is it necessary for the present, as it runs through a country which is never visited by civilized beings, or perhaps not inhabited by a native tribe. The same observation applies to the southern boundary-line of Yucatan, which it borders on Guatemala, the most northern state of Central America. This line passes through a country inhabited by a native tribe called the Lacandones, who avoid all communication with European settlers, do not admit foreigners among them. It is supposed that the boundary-line is formed partly by the course of the river S. Pedro, a tributary of the Mexican.
course of this river is very imperfectly known. On the south-west of Yucatan are the Mexican states of Chiapa and Tabasco, and here it is supposed that the boundary is not exactly fixed. It is partly formed by the river Usumacinta, but lies mainly between the principal branch of that river and its arm which is called Palisada. It seems to terminate on the shores of the Gulf of Mexico, at the Heads of St. Gabriel (near 10° 10' W. long.).

Coast and Harbours.—From the extreme extremity of the Heads of St. Gabriel a low, swampy, and wooded shore extends to the western entrance of the Laguna de Terminos. The Laguna is about 60 miles long from west to east, and more than a mile wide on an average. It contains several large rivers, among which are the Rio Palisada and the Pacaicata or Bateac, its waters are salt only in the dry season, and hardly brackish in the wet season. It seems to be deep enough for the largest vessels, and it is only nine fathoms deep from 15 to 30 tons, which are also flat-bottomed on account of the shoals at the mouth of the Rio Palisada, as the country contiguous to the banks of that river alone yields any article of commerce. The trade of the port is small. The present year, the season, and even the dry season is partly occupied by lagoons and swamps. The greater part of it is overgrown by low bushes. This low tract extends eighteen miles inland, at the back of the town of Sisal, so that a causeway has been made across the lagoon from Sisal to the capital of the republic. The port of Sisal is only an open roadstead, and large vessels are obliged to anchor more than two miles from the shore. It would seem that along this coast as far east as 81° W. long., good anchorage is always found for vessels of between 100 and 300 tons, which are of the usual Spanish type, rising in height about 10 feet above the sea, and at a few places higher. These hills are partly overgrown with bushes. A series of such hills forms a tongue of land, which separates a narrow arm or channel called Rio Lagartos from the main body of the sea. It does not appear that this narrow sea is navigable, nor is it stated whether there is safe anchorage along this coast west of Cape Catoche. In approaching this cape the sandhills disappear, and ships are covered with swamps and cut up by long lagoons. But in this part the low tract is overgrown with trees rising to 150 feet. The cape itself is low and lined by a line of sandhills, which are partly covered with high trees. The distance between this cape and Cabo de S. Antonio in Cuba, where is the strait which connects the Gulf of Mexico with the Caribbean Sea, is nearly 150 miles.

The eastern coast of the peninsula from Cape Catoche to 20° 15' N. lat. is well defined, and not quite so low and swampy. At some places there are sand-hills 20 feet high, which are here and there clothed with stunted bushes. At other places there is a sandy beach, backed by level ground thickly covered with trees attaining a height of 50 to 100 feet in range.
high hills, and where it has been crossed by travellers it is about 10 miles wide. The soil of this region is generally thin, and of moderate fertility; but it produces nearly all the grains, fruits, and plants which are cultivated in the West Indies, by means of which the produce of the soil is sold in the market towns. The water is drawn by machinery from the tanks or canals, and spread over the adjacent country. But as only a comparatively small portion of the country can be irrigated, the larger portion lies waste, and is overgrown by stunted trees, trees not being deep enough for the growth of large trees. The lower tracts in the depressions, which preserve a growth of grass during the greater part of the dry season, are used as pasture-grounds for cattle.

The southern part of Yucatan exhibits a different character. We became acquainted with a small portion of this region, the interior having never been visited by travellers or settlers of European origin. We know only the tract bordering on the two gulfs. The country bordering on the Gulf of Mexico, and containing the largest part of the Peninsula of Yucatan, is very productive of fruits and vegetables. There are some plantations of cacao and sugar. Vanilla and indigo are stated to be common in the woods, which cover the whole plain; the woods consist of large trees, among which the logwood is very abundant. The wood consumed in Europe and America is brought from these forests. The unhealthiness of this tract is attributed to the great abundance of water, and the great heat in summer. It is not known how far this low country extends eastward; but it is stated that about 30 miles from the Laguna de Terminos, the rivers of S. Pedro and of Pacaitun are united by a natural canal running nearly north and south, and it is probable that this natural canal occurs where the country begins to rise gradually. The country on the shores of the Gulf of Honduras and surrounding Ambergis Bay is similar in its natural features, its fertility, and productions, but it does not appear to be so generally subject to inundation, and it is less unhealthy.

Rivers.—The lower course of the Usamantla [Mexican States, vol. iv., p. 150] touches the southern boundary of Yucatan, and sends off one of its arms, the Rio Pialada, which traverses the plain, and, after a course of about 100 miles, reaches the sea. Its chief streams are the Maracaibo and the Macay. This river is about 200 yards wide, and deep enough for large vessels, but at its mouth there are extensive shoals, which oblige the inhabitants to use flat-bottomed river barges or bungos of from 15 to 20 tons. The Piaulata or Macay, and outstanding, is navigable to a considerable extent, but it is not navigated, as there appear to be no agricultural settlements on its banks. It runs westward, and falls into the eastern part of the Laguna de Terminos. The Champon River, which falls into the Gulf of Mexico, is navigable from the city of Pina to the cultivation of the land. The nature of the country has introduced a peculiar kind of servitude, which is not found anywhere else. Where the sotanos, or natural wells, are numerous, and yield an abundant supply of water, the aborigines are independent, and as it does not appear that the whites have acquired any exclusive right to these wells. But in other parts of the country, where such wells are rare or wanting, men and beasts would perish in the dry season if no care were taken for the preservation of them. Hence the proprietors have constructed on each of their numerous estates large tanks and reservoirs at great expense, as they are frequently more than a hundred feet deep; and this creates a relation with the Indian population which places the proprietor somewhat in the position of a lord under the old feudal system. The Mayas are obliged to attach themselves to some estate which can supply their want of water; and in return for the privilege of using the tanks, they come under certain obligations of service to the master. The Mayas attached to such estates are of small classes.
The aborigines of Yucatan had made considerable progress in civilization when the Spaniards arrived there in 1517. They wore cotton dresses, and lived in houses built of stone. It cannot yet be determined if the ruins of those extensive and magnificent buildings which have lately been discovered in several parts of the country, were erected by the race which still inhabits the country, or by a more ancient one which has become extinct. The most remarkable and best preserved of the ruins which, up to 1842, have been discovered, are situated at Uxmal, about 12 miles from Merida, and at Chichen, about 12 miles west of Valladolid. The present generation does not appear to be inferior in civilization to their ancestors at the time of the arrival of the Spaniards. They still live in houses built of stone, and wear a decent cotton dress.

Manufactures.—The cotton-cloth generally worn by the Indians and lower classes of whites was, till lately, only made in the families, but recently a cotton-cloth, with steam-engines has been established at Valladolid. Other manufactures do not exist. In some places the Mayas make hats from the leaf of a palm, which are exported to the neighbouring countries from Campeachy, and in the United States are known as Campeachy hats. Sackcloth made by the country-people is exported.

Commerce.—The commerce of Yucatan is of very limited extent. None of its agricultural products yield articles of export, except the Sisal hemp. The manufactured articles are Cottons, calicos, and sackcloth. The most important of these articles are derived from the forests, as logwood, deer-skies, wax, and honey. The imports consist chiefly of English and French manufactured goods, and spices brought from the East Indies.

Vulcanos.—The Yucatanos have shown some taste for literary pursuits. There are two colleges; one at Merida, called Minerva College, and another in Campeachy. The latter has six professors, and in 1842 there were 55 students, besides 13 more who were on the foundation. There are also schools for the lower classes, but we are not acquainted with their condition.

Political Divisions and Towns.—Yucatan is divided into five departments and eighteen districts, and contains 236 towns.

The capital, the city of the Indians, which is the north-west of the city, and is the seat of the government of the republic. It is about 25 feet above the sea-level, and built upon the ruins of an Indian town, which was destroyed by the Spanish. The streets are narrow, and laid out at right angles to one another. The side-walks are four feet wide, and paved with rough stone. The houses are well built of stone, and uniform in their appearance. The roofs are flat and the exterior finished with stucco. The middle of the streets is lowest, forming a passage to carry off the water. After heavy rains the streets are flooded to the edge of the walks, and for some hours nearly impassable. There are five fine squares, the principal of which is in the centre of the town, and surrounded by the cathedral, the bishop's palace, government house, and the dwellings of the wealthiest citizens. The cathedral is a vast structure, and built in the best style of the sixteenth century. There are also thirteen other churches within the city and the suburbs, and they are in general well built. None of the other public buildings are remarkable.

The population is about 20,000 individuals, the majority of whom are Indians and half-breeds. Still about 1000 inhabitants, almost all Indians: from this post are exported hemp, sackcloth, ox-hides, deer-skins, etc.

Valladolid is a considerable town in the interior, with more than 15,000 inhabitants. In the district north of the place the best cotton is grown, and lately (1841) a cotton manufacture has been established. It has a very beautiful cathedral. The climate is considered the healthiest in Yucatan.

Campeachy, on the Gulf of Mexico, is entirely built of calcareous stone, and stands upon a foundation of the same substance, which contains subterranean caverns of great extent. It is one of the most remarkable towns in Yucatan. Probably they owe their existence to the building materials which have been got from them. The streets are narrow and irregular, and have the usual appearance of those of Merida. Most of the houses are of one story.

Campeachy exports large quantities of logwood, wax, honey, and a number of vessels are built here, among a few, is the largest keel. A handsome playhouse has lately been erected.

In the interior are several other towns, containing from 3000 to 10,000 inhabitants, among which are Manta, Silax, and Zilbacchen. The last-mentioned place is the capital of the state of Campeachy, and the United States are known as Campeachy hats. Sackcloth made by the country-people is exported.

Where the boundary-lines of Yucatan, Guatamala, and the British colony of Belize are supposed to meet, there is a large tract, probably exceeding 30,000 square miles, almost a continent, and within which there is but one town that is inhabited, and, according to some reports, it is populous. The inhabitants are known by the name of Lacandones, and are stated to assist all intruders upon their neighbours, except that sometimes they bring them presents of curiosities, and the quality, and is grown by them to a great extent. Some persons assert that they have seen in this country, during a great distance, a very large and well-built town, and it is supposed by some travellers that when the Spaniards first tried to cross the country they were within a town of immense buildings have been erected which occur in Yucatan, and the ruins of which have lately excited so much surprise.

History.—The Spanish historians mention, that about a hundred years before their arrival, about 1429, a political revolution had taken place in Yucatan, in which the town of Mayapan was destroyed. One of the causes of this revolution is mentioned as the head of the province of Chi-che-ira, a name which is still applied to one of the most interesting and extensive groups of ruins. Yucatan was discovered in 1517, by Hernandez Cordova, who had been sent by Velasquez, the governor of Cuba, for the purpose of making discoveries. He sailed from Cape Hatteras to the vicinity of the Laguna, de Timins, and landed twice; he found the inhabitants were civilized, but warring. In the following year Juan de Grijalva, following his first arrival at the island of Cozumel, whence he sailed, the peninsula and along the eastern coast of Yucatan, for no good reason, and was killed. He also experienced the warfare disposition of the inhabitants. Cortes had subjected Mexico to the dominion of Spain, and sent, 1522, Bernal Diaz to conquer Yucatan, which he also accomplished, though not without an obstinate and prolonged resistance. Yucatan remained in the hands of Spain up to the time when the Mexican States acquired their independence. Nor did it experience the evils of internal warfare during the protracted struggle between the mother-country and the colonies (from 1810 to 1821) that ensued. It was always adherent to the government established in Mexico, and formed an
independence had been obtained, one of the states in the Mexican Federation. In 1835 the federal government in Mexico was, exchanged into a central government. This created much discontent in those persons who had some suspicion of governing the states of which they were citizens, and they constituted a party called the Federalists. For some time they tried only to influence the choice of representatives to Congress, but not succeeding, they began to agitate, and they succeeded in Yucatán. In 1839 the Santiago Iman, a militia captain, set up the standard of revolt in Tizimín, a small town in the interior of Yucatán, and proclaimed the Federal Constitution of 1824: he attacked the large haciendas, and was more generously afterwards driven from Tizimín. But he soon reoccupied the place, and gained the favour of the Maya Indians by offering them a discharge for the future from the contributions which they had to pay. The Indian problem was already becoming acute in the neighboring republic of Central America the aborigines, under the conduct of an Indian, Carrera, had begun a successful war against the president of the republic, Morazán, and, with the help of the federal government, had seized the port of Tizimín. The most important town of the Yucatecan coast, which was abandoned by the French in consequence of the defeat of General Iturbide, had now been captured by the federal troops. Yucatán was, for a time, a free state. The government troops sent against them were at first successful, but in the beginning of 1840 he succeeded in taking the important city of Valladolid. After this event Merida and the other towns submitted. In the summer of 1840 this state was again conquered, and the state of Yucatán, after the capitulation of 1824. Nothing was left but Campeche, the head-quarters of the Mexican general Rivas, with a garrison of 10,000 men. This place was besieged, and surrendered at the mouth of June, 1840. In 1841 the legislature declared the republic of Yucatán, which adopted a new constitution, which does not materially differ from the former one. The legislature consists of two houses, a senate and a house of representatives, and at the head of the executive is a governor. It is very probable that this city will remain in the hands of the federal government, which has the most powerful army in the country which lies between it and the other states of the Mexican confederation. It is the plain of Tabasco, a watery place, very thinly inhabited and extremely unhealthy all the year round. The attempt to cross this plain with an army was an almost fatal destruction to the army by disease. To invade the country by sea would require a much larger navy than the Mexican republic has at its disposal. It is however to be feared that the Indians, who compose four-fifths of the population, and by whose assistance the revolution has been effected, will turn their arms against the whites, though the latter for the present have avoided such an event by readily acceding to the revolution.

Y. lortetii, Allan's Adam's-Needle, has linear-lanceolate, even, straight leaves, with the edges bordered by fine callous notches. This plant is a native of North and South America. It was introduced into English and Dutch gardens a century since, where it is treated as a greenhouse plant. Its leaves are straight, and narrower and stiffer than those of the last. The panicle is also more dense and cylindrical. The flowers are white, and externally tinged with purple. It very seldom flowers in this country; and when this event takes place, the plant becomes branched, and, as it grows older, it is more and more thorny. Y. draconis, Drooping-leaved Adam's-Needle: the leaves linear-lanceolate, even, reflexed, crenate; the segments of the corolla spreading, somewhat recurved. This plant is very rare by Mr. Alton to be a native of South Carolina, where it flowers in October and November. The flowers are larger than in the last species, and are an inch broad and above two feet long. Clusius says that the Indians use the fibres of these leaves for the purpose of making a fine cord. These compositions of the rafter's of their huts together. Y. filamentosus, Thready Adam's-Needle: stemless, with lanceolate entire leaves, coarsely filamentosus at the edges. It is found on the shores of Virginia and Carolina, and is said to develop the finest fibres for the purpose of plaiting in this country, and blossoms in the autumn. Its flowers are panicle and pendulous, and of a cream colour. The leaves have their edges beset with long recurved threads. In the cultivation of these plants, they may be all propagated by offsets which are easily detached from the parent plant at any time during the spring and summer season. They should be laid aside in a dry place, for the wound caused by their separation to be healed; and when this is effected, they should be planted out separately and kept in compost till they have rooting. When propagated by seeds, those from abroad should alone be employed. The seed should be sown in spring in pots of light earth, which should be placed in a hot-bed, when the plants are soon up. When the plants have formed their first leaf, they should be placed out in pots of light sandy mould, and still kept in the hot-bed, but hardening them by degrees to the open air, to which they may be exposed from June till October, when they should be hardened off for the winter. They should occasionally have moderate waterings.

(Sir J. E. Smith, in Reece's Cyclopædia; Burnett's Outlines of Botany.)

YVERDUN. [Wayneck.]

YVERDUN, a town of the Canton de Vaud in Switzerland, situated at the south-western extremity of the lake of Neuchâtel, which is sometimes called the lake of Yver dun, where the river Orbe, called also Thicle, enters the lake. Yverdun is the capital of the district of the Canton de Vaud, and is the head of a district containing thirty-eight communes and about 12,400 inhabitants. The town of Yverdun had, in 1837, 3460 inhabitants, including its 'banlieue,' or communal territory. The town is well built, the streets are wide and regular, and there are some very fine promenades on the banks of the lake. Many families in easy circumstances reside at Yverdun, and the town carries on a considerable trade in cattle and agricultural produce. Fair held at Yverdun; steam-boat plies between Yverdun, Neuchâtel, and Bienne. Yverdun acquired a sort of celebrity in the early part of the present century in consequence of the institution for education, directed by Pestalozzi, which was established here in 1805. After removing to Buchsee, Pestalozzi became connected with Fellenberg, whose attention was also turned to the subject of popular education. [Horw.] In 1805 Pestalozzi removed his establishment to Yverdun, the town being him the use of an old castle, where he developed his peculiar system of elementary education, which has been the subject of much inquiry and much discussion. For information concerning Pestalozzi's system, or method, as he called it, we must refer the reader to the works written by himself, or 'Exposé de la Méthode élémentaire de H. Pestalozzi, suivi d'une notice sur les travaux de cet homme célèbre, son institut, et ses principaux collaborateurs,' by D. A.
Z.  

Z, like Y, was only found in the later Roman alphabet, XIX, from which it has been transferred to the alphabets of Western Europe. In the Greek series of letters it occupied the seventh place, the sixth being the property of the subsequently dismissed Vav or F. Two questions then arise which deserve an answer: how was it that the Greek alphabet was not completed by the addition of Z? And why was the Greek letter not supplanted by the Greek letter, if we account for the Latin letter G occupying the place which should have been given to Z? We would first observe that the Greeks were surrounded on the north by Slavonic races, with whom an abundance of z's has always been in favour, so that the early position in the alphabet of Z need surprise no one. In the second place, we strongly suspect that the genuine sound of the Greek Z in early times was not, as is sometimes stated, that of ad or de, but would be explained. For instance, the form Zeus in the Iliad would not surprise us, the long-sides of either Διος or Τιτανος, &c., or of the Italian Giove. [D; J.] Next looking to the Roman alphabet we are disposed to contend that the character G, which occupies the same position, is the same power, and that it was not the equivalent of the Greek Ν, for the second letter of the Roman alphabet, C, as it derived its form from the Greek Κ, merely changing its angle into a curve a change not unknown to the Greeks themselves, see the tables of the old Greek character under Alphabet. Its power was precisely the same, a fact for which we have abundant testimony among the Romans themselves.

C.] Ausonius, for instance, says, 'Prisim vice Gammme unccta est.' But if G originally represented a sound different from that of the Greek K, it is not likely to have belonged to it than that of our English J, when we know that the sound is still current in Italy, although they want a single character to represent it, and, secondly, when it is an undoubted fact that the two sounds are very apt to be interchanged. In our own tongue the very letter in question performs the two offices we are speaking of, in gender and get, even before the same vowel; and we once met with a child already ten years of age, whose ear and tongue could make no distinction between the two sounds of di before a vowel, of an English J, and of our initial y, are closely related. Those who read the ballads in Percy's 'Religions' will find many words where a z is heard; thus Menzies is pronounced Mingies. But if the Latin G and the Greek Z had originally the same power, as well as the same place in the alphabetical series, it becomes difficult to believe that the G alone of all the Latin letters did not derive its form from the Greek symbol. Now is the change so violent as would at first appear. If the Greek Z were written with its oblique shaft from north-west to south-east instead of from north-east to south-west (a supposition having little difficulty in it, if letters were originally pictorial), then the ordinary change from north-east to south-west would be accomplished. For the very near the true Roman G, which at times was not like the Arabic numeral 2, supposing it to look the other way. [Alphabet, p. 584, pl. iv., col. 6.] The permutations to which Z, liable have partly been shown above, and all of them are to be accounted for by a change from north-east to south-west.
which the "Remonstrant" had met with induced Zachariae still published a series of epistles which we may mention "Phaeton," "Das Schnupftuch," "Murner in der Hölle," the last two of which are the best among them. In 1747 he went to Göttingen, where he formed connections with men of congenial minds. In the following year he was appointed professor at the gymnasium (Carolino) of Brunswick, and the beneficial influence he exercised there on the development of the talents and taste of his pupils induced the duke of Brunswick, in 1761, to appoint him professor of poetry at the Carolino. In addition to the duties of the earlier German in 1762, he received the presidency of the printing and publishing establishments connected with the orphan asylum (Waisenhaus) of Brunswick, and of the Brunswick "Intelligenzblatt," to which he himself contributed a series of interesting and useful papers. In 1763 he resigned the superintendency of those establishments, which had prospered very much under his management, and confined himself to the duties of his professorship. From 1768 to 1774 he edited the "Neue Braunschweiger Zeitung" (the New Brunswick Gazette), for which he himself wrote much poetry and reviews. He died on the 30th of January, 1777.

Zachariae was one of the best poets of his time, and in the comic epic he has scarcely been surpassed by any more recent German poets. He is less celebrated, however, as a poet. He also wrote a number of sonnets, in light and pleasing style, and he himself set many of them to music. He made a German translation of Milton's "Paradise Lost," in hexameter verse (Altona, 1760, 4to.), a second and considerably enlarged edition appeared in 1763; this translation is weak, and not always faithful to the original. His "Fabeln und Erzählungen in Burkard Waldia's Manier" belong to his best poetical productions. His style is clear, plain, and correct. For the purpose of promoting the study of the German language, Zachariae began to publish a collection of the best specimens of the best German poets of the time of Opitz ("Auserlesene Stücke der besten Deutschen Dichter von Opitz bis auf gegenwärtige Zeiten," Brunswick, 1766-71, 2 vols. 8vo.). The number of this work was continued by Eschenburg, who published a third volume (1778, 8vo.). The first complete collection of Zachariae's works appeared at Brunswick, 1769-73, 5 vols. 8vo.). A second and cheaper edition, in which the translations from foreign languages are omitted, was published in 1772, in 2 vols. 8vo., and was reprinted in 1777. After his death, Eschenburg published a supplementary volume, which also contains a Life of Zachariae.

ZACHARIAS, KARL SALOMON, a celebrated German jurist and political writer, was born at Meißen, on the 14th of November, 1702, and received his early education in the great public school (Fürstenschule) of his native place. In 1727 he went to the university of Leipzig, where at first he devoted himself almost exclusively to philological and philosophical studies, but afterwards he took up the study of jurisprudence. He left Leipzig in the spring of 1729, and, being recommended by persons of distinction, he obtained the situation of tutor to the young Count Lippe, whom he accompanied to the university of Wittenberg, where he continued his studies for two years more, and when the count returned, he followed him over his grief-paid career. Zachariae, in 1735, carried into effect his favourite plan of becoming an academical teacher. He had not been privyadvocate for more than two years before he was appointed professor extraordinary, and in 1702 he was raised to the ordinary professorship in the university of Wittenberg. He had distinguished himself as an author long before this time, and had acquired considerable reputation as a philosophical and political writer. In 1743 he received an invitation to a professorship in the university of Heidelberg, which he accepted because in his situation at Wittenberg his leisure time was almost wholly occupied with the practical administration of justice, which formed part of his office, and thus he had little time left for literary pursuits. At Heidelberg, he lectured on law in all its departments, among which we may mention the public law of Germany, canon law, feudal law, and comparative jurisprudence. He always treated his subject in a philosophical spirit. His merits were rewarded by the title of Geheimer Rat of the grand-duchy of Baden, and in 1746 he was drawn away from his scientific and literary labours by the desire to throw more power into the hands of the government than we are enabled to judge of him, he was a liberal reformer with a strong leaning towards aristocratic principles. For this reason, during these years, he received two very honourable invitations, the one to Göttingen and the other to Leipzig, both of which he declined. He remained at Heidelberg until his death on the 27th of March, 1843, having shortly before been offered the rank of professor under the name of Knight von Lingenthal. Zachariae was one of the ablest of all philosophers, and few continental men have possessed so comprehensive knowledge of the legal and political nature of the various states of Germany and Europe as he did.

The following list contains his principal works:

1. "Handbuch des Kurfürstlichen Lehrrechts," Leipzig, 1786, 8vo.; a second edition was published by Ch. Z. Warschauer and P. A. Lessing, 1790, 8vo., entitled "Handbuch der Staats- und Kirchen Rechts," Leipzig, 1797, 8vo.; a sort of appendix to this work is his "Nachtrag über die evangelischen Brüdergemeinen," Leipzig, 1788, 8vo. 3. "Handbuch zu Französischen Civilrechts," of which the third edition appeared in 1795; also an "Handbuch zu den Büchern vom Staate," Stuttgart, 1820-22, 5 vols. 8vo.; a new and much enlarged edition of this work was begun in 1839, and completed in 1843, in 7 vols. 8vo.; it is the best work on political philosophy in the German language.

2. "Antheologie," 1762, 8vo.; a treatise on the duties of the modern Freistaaten, Heidelberg, 1834, in two parts, 8vo.; a very admirable treatise, the only fault of which is, that it assigns greater merit to the political men of Sully than they deserve. He also contributed valuable articles to the "Dictionary of the⊅jointly with Mittermayer, entitled ‘Kritische Zeitschrift zu Rechtswissenschaft und Gesetzgebung des Auslandes’ to the ‘Heidelberger Jahrbiicher.’"

(Brockhaus, Conversations Lexikon; Gersdorff Leipzig, genus jurisprudentialis fof 1812, p. 39.)

ZACHARIAS. (ZACHARIAH.)

ZACHARIAS, a native of Greece, succeeded Gregory III. in the see of Rome, a.d. 741. Liutprand, king of the Lombards, was then at the height of his power in Rome, in consequence of the support which the Roman and Pope Gregory had given to Trasmund, duke of Spoleto, and Gotteschall, duke of Beneventum, who revolted against Liutprand. Zachariah took a dispassionate view of their conduct, and his works appealed to Stephen, who was duke of Rome, and with the lessons of that city, to induce them to give up the alliance of the rebellious dukes, and to send messengers to Liutprand to sue for peace, which Liutprand willingly granted. D. Romano then joined their militia with the troops of Liutprand, who invaded the duchy of Spoleto, and obliged Trasmund to surrender to the king, who ordered him to take clerical orders, and appointed Anspurad in his place. Zacharias, in his letters to King Liutprand, urged that as Trasmund had seized the duchy of Rome, which the king had seized during the former calamities, and as Liutprand delayed the restitution, Zachariah went to meet him at Terni, when the king received him with great honours, and not only restored the duchy of Spoleto, but, to the duchy of Beneventum, received him as a servant, and of the Roman see a patrimonium or estate in the Sabinium, and other estates in the districts of Ancona, Osimo, Numana, and other parts. The peace between the Longobards and the Romans was restored without rancour.

In the following year, 742, Liutprand attacked the exarch of Ravenna with a powerful force. The exarch was unable to make head against him, and appealed to the mediation of Zachariah. Zachariah proceeded to Ravenna, but in his absence wrote to Liutprand, announcing to him his intention to visit him in his own capital, Pavia. The novel office, in the relations between the pope and the king of the Lombards, and the ministers of Liutprand, was
oured to prevent its being carried into effect. Zacharias however proceeded to Pavia, where he was received by Luitprand with great respect, and, after some debate, the king yielded to the request of the pontiff, and restored to the Greek empire certain territories which he had seized upon the exarch. The pope then returned to Rome, being honourably escorted, by order of King Luitprand, as far as the Po. In the following year Luitprand died, and was succeeded by his nephew Hildebrand, who, being deposed after a few months for his ill conduct, Hatches, Duke of Milan, was proclaimed king, A.D. 1073, hastened to the king's camp, and succeeded not only in making him resist from his attack, but, by his exhortations and remonstrances about the vanity of earthly greatness, he made such an impression upon the king, that he was afterwards abdicated, and returned to Rome with his wife and daughter, where, at their own request, they received the monastic habit from the hands of the pope.

Latches retired to Monte Casino, and his wife and daughter with him, in a manner that is not recorded, and about the same time Carlemon, Duke of Austria, and second son of Charles Martel, renounced his office in favour of his brother Pepin, and proceeded to Rome, where he became a monk, and founded a convent on Mount Soracte.

In the year 751, Pepin, who had been sent to purchase Christian slaves in Italy, and even at Rome, whom they sold to the Saracens in the Levant, on account of their heavy ecclesiastical censures, and assumed many of those who had been sold, and restored them to their liberty.

About the year 750, Pepin, who governed France, with the title of Maire of the Palace, in the name of King Childeric III, sent ambassadors to Rome to represent to the pope that Childeric was unfit to reign, and had never been crowned, or invested with the regal robes, and it was impossible for him to have a king capable of managing the affairs of the state; and that the leading men of France wished to proclaim him, Pepin, as their king, if the pope would return to France. Pepin, on this occasion, left Childeric to Zacharias is said to have answered that it was meet that he who had already the real power and the government of the state should be king, upon which the Frankish leaders and nobles assembled in a general assembly deposed Childeric, and his heir, named Charles Martel, from the throne, and invested Pepin with the regal robes.

The abbot of Zacharias (for the abbot is certain, though he particulars of it are obscure) to this violent change of dynasty is the only questionable act that we know of this pope, who in other respects appears to have been a lover of justice and religion, as himself felt, until his conscience till he received absolutation from Stephen II., the successor of Zacharias, and was crowned again by him at Paris.

Pope Zacharias died in the year 752. He is said to have been very generous towards the clergy and the people of Rome; he repaired the Basilica of the Lateran, and built several churches. He translated into Greek the dialogues of Pope Gregory I., or the Great, for the benefit of his countrymen. His epistolary correspondence with Boniface, Archbishop of Mainz, is found in Henrici's "Collegii Concilia.

(Platina e Panvinio, Vite dei Pontefici; Muratori, Antichità d'Italia.)

ZACHRIEVEN, CORNELIUS and HERMAN, brothers.

Their name is sometimes written Sallieven. Cornelius was born at Rotterdam in 1600: he excelled in pictures of horses and soldiers, in the style of Teniers and Bruyaer. His scenes, which were always sketched from nature, are full of truth and character, but as paintings they want that brilliancy and transparence of colouring which distinguishes the works of many of his countrymen. He painted also landscapes, and made many spirited etchings after his own designs. Some of Cornelius's foregrounds are particularly clever, being groups of various utensils or implements, characteristic of the occupations of the characters of the picture. The year of his death is not known, according to the Dutch writers, but in Pickington's Dictionary 1673 is given.

Herman Zachielven was an excellent landscape-painter. He was born at Rotterdam in 1601, and was the pupil of J. Van Goyer; but he lived the greater part of his life at Utrecht, where he died in 1683. Herman's landscapes, which consist generally of views in the vicinity of Utrecht and of the Rhine, are distinguished by great transparency, from being coloured like those of Wolfaumen. His earliest pictures are such simple views of nature as the various sites afforded, but in his later works he generally selected various picturesque points, which he composed into one picture; he sometimes introduced many small figures into his works. Herman made nature in black chalk, which are much valued by collectors: he executed also a few spirited etchings. D'Arzensville says that Herman Zachielven visited Italy, and spent some years there, but very little is known of his life after any such visit, and still greater reason for supposing the statement to be incorrect is that there are no traces of Italy in any of his studies or pictures.

(Houbrouken, Groote Schouburg, S. ; D'Arvensville, Abbé de la Congrég. de l'Ordre te, Av. ; ZACYNTHIUS. [Zante]. ZAGROS, MOUNT. [Persia].) ZAHLLE [Syria, p. 472.]. ZAIDA [Syria, p. 472.].

Zahle is the largest river in Western Africa south of the equator. It is called by the natives Mosun Elarabli, that is, the Great River, or 'the river which absorbs all others.' The upper part of the river has not been visited by Europeans. According to the information obtained from the native traders and from the principal inhabitant of the Upper Zahle, the river flows from the south to the north; and its source is supposed to be in one or two degrees north of the line. But it is certain that another great branch originates in the interior far to the south-east from its mouth, and this branch is called Congo.

In the Middle Ages the term Zahle was applied to a branch of the Congo which is probably in general about 250 miles, from its embouchure in the Zaire to Captain Tuckey. At that distance from its mouth the river expands to the width of two, three, or even more than four miles, and flows with a current of two or three miles an hour. This upper part of the river enters an elevated country, which is probably more than 500 feet above the sea-level. The country is hilly, with the exception of some tracts of fine sandy beach, but the hills are of moderate elevation, and rise with a gentle ascent from the margin of the river. The villages are chiefly composed of small huts, with thatched roofs, and many rocky promontories of marble jet into the river. A considerable portion of the country is fit for cultivation on the summits and on the sides of the hills, as well as in the valleys. It is also much more inhabited than farther down, and villages are frequent. The current is far from being so luxuriant as is usual between the tropics, and the hills are frequently barren, and destitute of trees, which only occur in the ravines and round the larger villages.

The Zaire begins to descend from this upper terrace about 200 miles from its mouth. The bed of the river gradually narrows to a mile, and then it falls over the Upper Sangalla or rapid, which is formed by a ledge of rocks running across the river, under which the current runs with great force. The Zaire now begins to flow with great rapidity between high rocky masses. Ten miles lower down is the Lower Sangalla, where the river is crossed by a great ledge of slate rocks, which leave only a passage of half a mile across the river, which flows 200 yards wide, through which the stream runs at least eight miles an hour, forming whirlpools in the middle, whose vortices occupy at least half the breadth of the channel, and must be fatal to any canoe that should attempt to pass them. Below this rapid the river is filled with rocky islets; the great breadth, however, diminishes the velocity of the stream, so that canoes easily pass. About 15 miles below the Lower Sangalla begins the narrows, where the river, from more than a mile, suddenly contracts to less than half a mile, and in many places it is hardly 200 yards wide. (Vol. XXVII. 5 A.)
These Narrows are nearly 40 miles long, extending from Inga to Sondie Point. Though the bed of the river is narrow, it is generally full of rocks. Before the river leaves the Narrows it forms a cataract called Yellala, where the river descends over a bed of mixed slate, and falls about 30 feet perpendicular in a slope of three yards. A little above Sondie Point a ledge of rocks stretches from the northern shore about two-thirds the breadth of the river (which is here about half a mile wide), the current breaking furiously on it; but near the southern shore a smooth channel is left, with little or no velocity on the current, is the only obstacle to the ascent of boats. The tide is perceptible as far as Sondie Point, where it rises about six inches, and from this point the river begins to be navigable. Between the Upper Sangalla and Sondie Point the general course of the river is from north to south, and from Sondie Point to the sea nearly due west.

The country extending on both sides of the Zaire from the Upper Sangalla to Sondie Point rises considerably higher than the general level of the upper terrace. Contiguous to the river's bed there are high hills consisting chiefly of mixed slate. They are very steep, in many places precipitous, and destitute of all vegetation. In some spots, where the current has been turned aside by rocky points, the river has deposited its mud, and formed little islands which are covered with reeds. A small quantity of Indian corn is grown. The declivities of the rocky masses are intersected by several little valleys, which penetrate a few miles inland, and in which some plantations of manioc and Indian corn are met with, and many of the palms. The sides of the river, which in general appear to attain an elevation of 1500 feet above the sea-level, presents an uneven plain, in general destitute of trees, but having a soil sufficiently deep for the cultivation of the country's most valuable article, vegetable marrows. On this plain there are numerous small villages surrounded by mimosa, Adamsonia, and palm-trees. The soil is of a hard clayey nature, and is incapable of being worked in the dry season, but is sufficiently productive with manures, and by the heavy rains and with the aid of a heated atmosphere.

From Sondie Point to Lemboor, a distance of about 15 miles, the river runs south-west. This part of the river is characterized by a succession of whirlpools, which are so violent that no vessel can approach them; even the eddies occasioned by them are so forcible as frequently to resist sails, oars, and toying, and twist a boat round in every direction. At Lemboor Point the river again widens to a breadth of a mile, and runs westward with a regular but not a strong current to Bland, Embomma, about 20 miles distant. The country on both sides of the river between Sondie Point and Books Embomma Island does not differ in its physical character from the rocky districts further north.

At the Books Embomma Island the valley in which the river flows widens considerably, the rocky masses receding so far from one another as to leave a space about three miles in width between them. This space is half occupied by the two arms into which the river divides, and half by the islands which lie between them. The bed of the river is here about a mile and a half across, and its current in the mid-channel varies between a mile and a half and two miles an hour, but inshore on both sides it is only stagnant, and sometimes even foreshortened and widened to a considerable extent. The small counter current in the mid-channel is 15 fathoms. The islands are composed of schistus, and are barren: but along their northern side is a strip of low ground of great fertility. The hills on both sides of the valley are rather high and rugged, and are covered with bushy trees, and large trees which grow in the crevices of the rock. On their flatter summit, the under stratum, consisting of a compact clay, is covered with a black soil which seems capable of producing various kinds of grain.

Near 13°0' E. long., or about 50 miles from its mouth, the Zaire enters a valley which is about 10 miles across, and which does not materially change in width to its embouchure. One-third of this distance, or less than 20 miles, the flows between two high rocks is divided into three arms, of which the northern is called Maxwell's River, the middle one Mamballa River, and the southern Sonio River. The Mamballa River, also called the Bont River, because it is generally used by the vessels navigating the river, is filled with dry shoals, the channels between which are very winding. The depth of the channel north of the shoals varies from 1 to 15 fathoms, but the southern channel of the river is from 7 to 10 fathoms deep close to the southern bank. The current does not exceed two miles an hour. The three arms of the river are protected by several large and shallow channels which divide the tract between them into several from two to six miles in length. These islands rise several feet above the level of the river, and their shores are formed by a stiff clay, which on the margin of the river, and into which the current of water is condensed, has formed a high reedy grass and thinly scattered with palm-trees, in many places near the banks of the river the beds low and of great fertility.

Near 13° 20' E. long., the whole body of water is in one channel, which in the vicinity of the point falls two miles wide, but by degrees it widens to three, which is its width at Fathomless Point: this cape is considered as being situated on the northern side of the river. In this part the river is distinguished by its great rapids and cascades. The current even at a short distance the banks varies between four and six miles a mile. Though every afternoon a sea-breeze springs up, trying to enter the river generally find their way frustrated for several days, and they only succeed with difficulty uncoupled from the rapids of the shore. The great body of water discharged by such a rapid current has scooped out a channel two miles in width, but very deep. Above Shark Point, which is a southern side of the mouth of the river, it is seldom more than one mile across, but the whole bed of the river is incomparably unfathomable. Captain Vidal however ascertain depth varied between 200 and 450 fathoms. He observes that the great force of the current is apparently sensibly lessened by the rapidity with which the river passes the rocks at the Zelina cape, and this has suggested the supposition that a very considerable number of subterraneous passages under the slate rocks, depending, in the direction, where the river contracts its bed and forms the Narrows, and rising again below the cataract near Fathomless Point, where the regular current is disturbed by an eddy in the mouth of a large island, and two other islands that divide it from 14 to 20 fathoms in depth.

The immense volume of water discharged by the Zaire into the Indian ocean, compared with the quantity of water which passes over the rocks at the Zelina cape, has been a matter of great surprise, especially as it is not sufficient to turn a mill falls into the Zaire below cataract; and this has suggested the supposition that a very considerable number of subterraneous passages under the slate rocks, depending, where the river contracts its bed and forms the Narrows, and rising again below the cataract near Fathomless Point, where the regular current is disturbed by an eddy in the mouth of a large island, and two other islands that divide it from 14 to 20 fathoms in depth.

The water of the Zaire appears to possess some peculiarities. Thirteen miles from the entrance it is fresh and of a dingy red colour. After being kept 40 days it ferments, and for some time remains in a putrified state. A silver plate immersed for half an hour is greatly discoloured, and requires repeated cleaning to remove the stain. After being preserved in a bottle for four months, it lost its colour and became perfectly clean and devoid of any sediment.

It was formerly asserted that the tide did not make an impression on the current of the Zaire, but it has been ascertained that it causes the reflux of the stream very perceptibly as high up as the lower commencement of the Narrows, and is experienced in the river to the point where it amounts to from 12 to 16 inches. But though it causes the water to be dammed up and a counter current to arise both sides, yet, strictly speaking, the current in the middle of the river is never overcome by the tide.

The duned banks bordering the Zaire rise low and swampy country. It is principally covered with two different kinds of mangrove, the one a low bush, and the other a stately tree, resting on a mass of roots sprouting twenty feet above the ground, the trunks often rising to the height of one hundred more. Most of them are protected...
Aristotle said, "Dreamers see great things." Marcian lived a long time, and was a great learner. Clemens could not say what he thought. Greeks of the ancient world are often called "growing trees," and are covered with clusters of trees. The islands, which are frequently seen rising from the river, appear to be portions of the land, scattered here and there above the surface of the current. They are formed of rushes, reeds, and other plants, which are covered with birds. Occasions yest they drift a long way seaward, and vessels are sometimes jerked by them. The southern side of the entrance is formed by a peninsula, called Point Papua, or Point of the Bitter Pacific, which is so called that to seaward is called Point Papua or Point, from a pillar which was erected on it, as at several other places, by the early Portuguese navigators. The cape, called Shark Point, lies eastward, and constitutes with Greek stream Point the entrance of all the rivers. The peninsula, on which the two promontories are situated, has evidently been formed by the combined deposits of the sea and rivers, as the external or sea shore is composed of quartz sand, forming a steep beach, while the internal or river shore is composed of gravel. (Tuckey's Narrative of an Expedition to explore the River Zaire; Narrative of Voyages to explore the Shores of Africa, Arabia, and Madagascar, under the direction of Commodore J. L. Beale.)

ZALEUCUS (Zaleuros), celebrated legislator of the Epizephyrian Locrians in Southern Italy, is said to have been the first Greek who drew up a code of written laws. Marcian Heracleot, 313; Clemens Alexand., Stromat., p. 304; Strabo, vi., p. 259. It has been supposed that the term deme is conceived from this word, but it is not certain. The laws among the Greeks must be limited to the Greeks of Italy, since it is stated that Zaleucus derived many of his laws from the Cretans, Lacedaemonians, and the Arcadians. He is supposed to have had the Cretans and Lacedaemonians as written laws at that time, and, as a result, we must acquiesce in the common tradition that Zaleucus was the first of all the Greeks who composed a code of written laws. He lived in all probability about 600 B.C., but his hopes were the start of all the legal legislators, who are mixed with fable. According to Suda, who describes him as a native of Thuri, Zaleucus was originally a slave and a shepherd; whereas Diodorus xii, 20 calls him a man of good family. He is further said to have been called upon by a Minerva in a dream to be a legislator for the Locrians; and when the Locrians applied to the oracle about the means of getting rid of their political disturbances, they received a command to legislate for themselves. When Zaleucus announced his political constitution, he was executed by burning, and as a result he left a code of laws for them. Suda: Scholarid ad Pindar. Olymp., x. 17; Valer. Maxim., i. 2; Ext. 4; Aristotle, i. aap Clem. Alex. Stromat., i, p. 326. A great portion of his laws was derived from the code of laws of his father, but he was the first who fixed punishments for the crimes enumerated in his code; whereas before his time the punishment had always been left to the discretion of the judges. His laws, of which several specemes are still extant, were according to the unanimous opinion of the ancients very severe, but the Locrians observed them for a long period, during which they were called the "most observant of laws and order" (kávovitpa) of all the Greeks. (Zenobius, iv. 10; Diodoruss., xi. 606; Velleius Paterculus, Proverb., x, 50; Marcian Heracleot, 313, loc. cit.)

The code of Zaleucus embraced the religious and moral as well as the civil and political duties of the people, and entered so much into the detail of private life that it was termed upon by the ancient world the "Zaleuctic Code." It should be distinguished from other duties. Although Zaleucus, as has been shown incontrovertibly by Bentley, must have lived before the time of Pythagoras, both Suidas and Diodorus call him a disciple of that philosopher, an assumption which is corroborated by the fact that he left all practical wisdom to Pythagoras, as in the case of the Roman king Numa Pomphilus, who is likewise called a disciple of Pythagoras. The common story about the death of Zaleucus is as follows: One day, in the course of the day, he judged that the citizens of Locri ought to enter the senate-house in arms; but on one occasion, while they were at war, Zaleucus, forgetting his own law, entered the senate-house as a warrior; and when one of the persons assembed called out to him that he was violating his own law, Zaleucus threw himself on his sword, and thus punished himself. Extracted from Homer, I. i, p. 62. But the same story is related by others of Charonidas, with whom Zaleucus is frequently confounded by the ancients themselves (Valer. Max., vi. 5, Ext. 4; Diodorus., xii. 20; and Suidas states that Zaleucus fell fighting for his country. The contradictions and fables which occur in the history led some sceptical writers among the ancients, such as Timaeus, to doubt that a legislator Zaleucus ever existed.

ZAMIA (Hannibal: Numida.)

ZAMBI. A genus of plants belonging to the natural order Cycadaceae. The name Zamia is applied by Pliny to such cones of the fir-tree as spilt whilst they are upon the tree. It was first applied by Pliny to trees of the genus, but the name Zamia is now used for a single cylindrical trunk, increasing by the development of a single terminal bud and covered by the scaly bases of the leaves: the wood consists of concentric circles, the cellular tissue between which are exceedingly loose, the ligneous tissue being hard and tough. The trunk is covered with the leaves are pinnated, not articulated, and have a gyrate vernalion. The flowers are dioecious; the male flowers are arranged in tesselated catkins with abrupt scales, the female flowers are in ovary, sessile at the under side of each scale. The female flowers are composed of several scales, the style having two at the under side of each scale. The species are found in the tropics of America and Asia, and also at the Cape of Good Hope and in New Holland. A. sprante, has leaves very smooth, somewhat curved, with a few spinous teeth at the extremity: the catkins smooth, with potted scales in the female, and wedge-shaped ones in the male flowers. This plant is a native of New South Wales. The cone is about half the size of a man's head, and composed of nuts about the size of a chestnut. These nuts are eaten by the New Hollanders, but on being tried by English settlers produced sickness. Their flavour is not unlike that of chestnuts.

Z. euphali, Bread-tree Zamia, has lanceolate, spinous, smooth, entire leaves tapering at the base; the scales of the catkins abrupt, obtuse, pointless. It is a native of the south-eastern parts of southern Africa. It grows on the tops of dry hills, especially where the ground has been cleared for cultivation. It is used as a source of building materials. The tree reaches a height of 6 or 7 ft. Tindberg states that when the stems become old they are broken through by the Cajures and Hottentots, who collect the pith and the tip up in the skin of a sheep or cow which has been previously well rubbed with grease. It is then buried in the ground, and after remaining there till it becomes putrefied, it is taken up and bruised between two stones, and then forced into little cakes about an inch in thickness. These cakes are baked in wood-ashes, and then eaten by those who prepare them as a great luxury, though they are not at all palatable to a European taste.

Z. forsteri, Broad Rusty-leaved Zamia, has elliptic-oblong pointless leaves, copiously serrated from the middle to the extremity; the leaves are covered with short, hairy, yellowish, ridgeless spines. The plant is a native of the West Indies, and is said to have been grown at Hampton Court in the time of King William. This plant is said by Herman to yield a white mucilaginous gum, which is a stimulant, and acts on the stomach; it has a nauseous odour and an unpleasant taste, arising from the existence in it of a peculiar proximate principle. This may be removed by boiling, or roasting, &c., when some of the taste form a nutritive food.

About seventeen species of the old genus Zamia have been described. Eight of these are now placed in the genus or subgenus Arthuria, which is characterized by having the leaves articulated with the rachis of the frond-like midrib; there is also a preparation in the rudimentary stamen to form a two-celled anther, while in Zamia the
leaflets are confluent, and the pollen is not disposed in two lobed masses.

The genus Zamia has many representatives in a fossil state. Of the sixteen species that have been discovered, twelve resemble so nearly the recent species that they have received the same designation. The remaining four differ in the exertion and venation of their leaves, and hence they are placed under the fossil genus Zonites. The principal fossil discoveries have been made in the limestone and oolitic formations. Two fossil stems nearly resembling those of Zamia were found by Dr. Buckland in Portland stone. These are made by Brongniart to constitute the genus Mantellia, a name given in honour of Dr. Gideon Mantell.

ZAMORA, the name of a town of Spain, and, both under the division into kingdoms and the division into electoral districts decreed by the Cortes of 1822, the name of the province of which Zamora is the capital. The town of Zamora is situated on the right bank of the Duero, 118 m. by road from Madrid; it is situated 46 miles westward of Valladolid. The town is surrounded by walls, in which there are eight gates. The suburbs have nothing to recommend them to notice. The streets of Zamora are narrow, the houses lofty, and the general aspect of the town is sombre. The churches and the town-house are the finest buildings. The promenades are agreeable, and there is a fine bridge across the Duero. Zamora contains a cathedral and 22 parish churches. Before the suppression of the monastic orders there were 10 convents, 10 of which were for females. Zamora was a bishopric, a suffragan of the Archbishop of Santiago. There is little trade or industry of any kind; but there are a few hatters, tanners, dyers, manufacturers of woollen-stuffs, and distillers. The ruins of the house of the Ojde are shown at Zamora. The feast of the patron saint, San Juan-Sarius-Hermosa, is celebrated in the city. The Cortes have twice assembled in the town, in 1297 and 1302. Population, in 1833, 10,000.

The province of Zamora (under the ancient division), in the kingdom of Leon, bordered on Portugal, and extended eastward on both sides of the Duero river, being thus cut off from the north by the spur of a range of mountains which forms the frontiers of the province of Salamanca. This mountainous province is composed of the ancient province of that name, the northern part of the district of Toro, and the greater part of the duchy of Benavente. It is about 86 miles in length (from north-west to south-east), and 43 miles in breadth (from north-east to south-west). The Duero enters the province near the middle of the south-east border, and, flowing from a little south of east to a little north of west, nearly bisects the province. On reaching the north-western border it makes an abrupt turn to the south, and flows in that direction till it meets the Tormez at the south-west angle of the province. The Tormez forms, for a little way, the boundary between the provinces of Zamora and Salamanca. In its course from east to west the Duero receives first the Sequillo and then the river Tormez from the north. The Sequillo receives from the west the Tera, a mountain-torrent, which issues from a lake near the borders of the province of Orense, and has the whole of its course in the province of Zamora. The bed of the Duero within the province, and for several leagues on each side of the Tormez is broad and precipitous to admit of their being used for irrigation. The north-west portion of the province is mountainous; the rest is a high plain intersected by deep ravines and river-channels. The soil is generally fertile; the mountains are well wooded. The climate is agreeable in spring and autumn, but the cold of winter is severe. There are some mineral-springs in the north of the province; turquoise are found in the vicinity of the town of Zamora, potteries near the town of Toro, and saltpetre is collected from the soil in some places. Agriculture and every kind of industry are at a low ebb. A good deal of charcoal is prepared, and some wine of a low quality exported. But the roads are in so wretched a condition as effectively prevent any extensive exportation of the staple agricultural produce.

Toro, the capital of the ancient district of that name, included in the modern province of Zamora. It stands on the right bank of the Duero, about 13 miles east of Zamora. The town is rectangular in form, and has a wall and six gates. The streets are wide, both houses mean. There is a collegiate and 18 parish churches.

Benavente, the chief town of the ancient duchy of the same name, which, along with its title, is now included within the electoral district of Zamora, is situated 66 miles north of Zamora and 42 north-west of Valladolid. It contains 9 parish churches. The palace of the Dukes of Benavente is an antient and extensive building. Population, in 1833, 5,190.

ZAMORCA [MEXICAN STATES].

Zamora is the name of a town in the Mexican State of Zumpango. It is situated on the south-western side of the state, about 70 miles east of Mexico. It is a manufacturing town, with a population of about 10,000. The name of Zamora is also given to a town in the State of Guanajuato, about 30 miles south of the city of Dolores. The town is a manufacturing centre, with a population of about 5,000.

Zamora City, the capital of the Mexican State of Guanajuato, is situated on the north-western side of the state, about 100 miles south-west of Mexico City. It is a manufacturing town, with a population of about 30,000. The name of Zamora is also given to a town in the State of Tamaulipas, about 50 miles east of the city of Ciudad Victoria. The town is a manufacturing centre, with a population of about 5,000.
The battle of the eagle was not surrendered to become the fact, but it was a serious consideration of the crown domains over the annexed dishonored as a remnant of his satisfaction, expressed much sympathy with him, presented to him in a letter. And, according to his wishes, he was released from his service.

Zamoyski was a man of great influence, and the people of Cracow elected him mayor. He was a member of the crown council, and was a leader of the crown domains. He was a man of great influence, and the people of Cracow elected him mayor. He was a member of the crown council, and was a leader of the crown domains.

crossed that he announced his resolution not to keep the promises he had made while a prisoner. This breach of faith elicited a pamphlet from Zamorski, published in 1690, with the title 'Facilitations inter Donum Austrianum ac Regem Polonicum et Ordines Regni Transactae, Scripta aliquot.'

The next seven years of Zamorski's life were consumed in a difficult struggle between foreign foes against whom he had to make head, and domestic factions from whom he had to wring a reluctant support. The king was not his friend, for Zamorski thwarted his wishes on many occasions, but could not dispense with his services. In 1641, the grand-chancellor baffled the Ottoman army in 1501-2; barred the retreat through Poland to the Tar- tars, who had made a predatory incursion into Hungary, in 1633; defeated the Turks in Wallachia in 1655, and again in 1657, 1658, and the Swedes in 1657. After the current of consciousness that his physical powers were giving way, he resigned the command of the army to his lieutenant, John Charles Chodkiewicz. From this time till 1603 Zamorski remained in retirement, occupied with his colonies and literary pursuits. The fruits of the latter were given to the world under the title 'Dialectica Chrysippa.'

He emerged from his retreat in 1603 to attend the Diet, and there is a wild grandeur about this the closing scene of his public life. The first wife of Sigismund III., an Angelen, disappeared, was dead, and he had married his sister, Zamorski, who had opposed the first marriage, was still more hostile to this: he was firmly convinced that the interests of Poland required an innermarriage with the royal family of Russia. The debate became vitally important; the chancellor, literary dispositions, had resolved to take no part in it, but the contagious excitement of the scene rendered him incapable of adhering to his resolution. He caused her seal to be placed near the throne, and after apologising for this liberty on account of his wife, if a young princess, presumed to address the king in a strain that has rarely been heard by princes. He declared his opinion that the king should concentrate his attention on the Swedish war with a view to terminate it; he reminded him that he had often before sacrificed the interests of the state to his own private ends; he protested against the marriage with an Austrian princess as likely to be fatal to Poland. Nor did he stop here: he accused the king of intending to secure the crown for his son in violation of the constitution, and of correspondence clandestinely with foreign powers; and he reminded him in a tone of increasing asperity that the Poles had ere then depoised and banished kings with whom they were offended. Sigismund, irritated by such language, replied with equal violence, and at the close of his speech laid his hand on his sword. At this the senate and deputies quitted their seats in a body with threatening murmurs; but the voice of the old chancellor was heard above all the din—Withdraw your hand from your sword, prince; do not oblige history to record the disfraces and your last action.

At the close of the Diet Zamorski retired again to his estates. On the 3rd of July, 1605, his attendants, who had fancied him sunk in meditation, found on approaching his chair that he was dead.

Zamorski was an elegant scholar, an accomplished diplomatist, and a successful general. That he should have been able to keep himself at the head of affairs during a period of nearly thirty years, in so turbulent a state as Poland, is of itself a guarantee of the power and energy of his character. His strength was his own even at this disaster of time, are calculated to please by their elegance, and by the knowledge of human nature that they display. His stern stoicism was the necessary consequence of a highly cultivated nature forces to endure the better part of his life with the fatigues of a fierce and vigorous state.

The part of his career upon which the mind feels most pleasure in dwelling, consists of the occasional retirements from public business, during which he devoted himself to colonising his estates and promoting literary institutions. About 1645 he laid the foundations of Novy Zamose, distant about two miles from Stary Zamose (old Zamose). He encouraged manufactures there, and fortified it so strongly, that it came to be regarded as one of the chief defensive lines of the Tartars. He established a printing-press, which became celebrated for the beauty of its impressions. On the 15th of May he opened the university of Zamose, to which he attracted the most eminent scholars of the nation, with a solemn inaugural oration. He granted lands in perpetuity to some of his valets, and encouraged the adoption of improved methods of agriculture.

Interesting particulars respecting these labours of Zamorski are contained in the narrative of two journeys made by Father Vasovzi to Poland to visit Zamorski, published in 1626 by J. W. Niemeyer at Warsaw, in 1622, from a MS. in the Alumbra Library at Rome.

John Zamorski II., born in 1626, was the grandson of the preceding. He was created, soon after he obtained his majority, castellan of Kalische, and was present at the capture, in 1651, of Warsaw, which was accomplished that king in his campaign against the Turks, in 1651, and earned by his bravery the appointment of palatine of Sandomir. He distinguished himself equally in the disastrous War of Succession, when Poland was defeated by the Swedes at Parnawa, and again at the hereditary fortress Zamose; and it was to this vigilant king, as commander of Warsaw, that Marshal Witczenski, the President von Ersk, and other important princes were intrusted. In 1659 he commanded the army which opposed the encroachment of John Casimir. In 1663 he was one of the nobles who remained faithful to John Casimir, and was mainly instrumental in effecting the disentomb of the insurgents under Chwiedereki. John Zamorski died suddenly at Warsaw, on the 2nd of April, 1665, where he had resided for two years. He was the third son of a family by wife, daughter of the Marquis de la Grande d'Arquin, and called in Poland La belle Francaise. Afterwards married the great Sobieski. Zamorski died without heirs of his body, his estates passed to his two sisters.

Andrew Zamorski, a younger son of a descendent of these two sisters, who had inherited the fief of Zamose born at Bielun in 1716. He received his education at the college of the Jesuits at Thorn, where he received his degree of Doctor in Law in 1732. In 1735 he was created a membro of the Polish visit foreign universities. He passed two years in the university of Liviltiz in Silesia; in 1739 he visited Paris, where his favourite studies were mathematics and jurisprudence; and he returned home in 1740. Finally, the brothers engaged in agitation about the loss of the inheritance, he reconciled them by giving up his share, and entered the service of Saxony. In 1745 he obtained the command of Prince Albert's regiment. In 1749 he quitted the army and returned to Poland with the rank of major-general. He was appointed marshal of the prince of Smolensko, an office which put it in his power to reform many abuses which had crept into the judicial administration of the province. In 1760 he emancipated the Jewish population of the province, and a greater number declined fiercely against the innovation. At the first Diet held after the death of Augustus III. (1763) Zamorski contributed much to the passing of a bill for the reform of administrative abuses. In 1768 the king of Prussia, in a treaty with Charles Alexander, gave great deal. The influence which this appointment enabled him to exercise over every branch of administration, and to employ in giving a better organization to the army and the educational institutions of the kingdom. When the Wars of Russia, in the Diet of 1762, proxied Ukraine. and they contain two books of letters, in which are particular
of his life. He died at Heidelberg in 1590. G. Gallizoli of Bergamo has written a biography of Girolamo Zanchi, published at Bergamo in 1783.

Francesco Zanchi, father of Girolamo and first cousin of Paolo Zanchi above mentioned, wrote a work, 'Commentarius de Rebus a Georgio Hemo praeclare gestis in primo adversus Maximilianum Romanorum Regem Bello a Venetis suseipto.'

'Tiraboschi, Storia della Letteratura Italiana (LAMCOSTLO), p. 459.'

ZANZIBAR is a country situated on the eastern coast of Africa. It does not appear that this name is in use among the natives or neighbouring nations who visit the country, and it is probably a corruption of Zanizibar, the largest of the islands belonging to it. There is also some difference of opinion respecting the extent of the country, some considering it to be bounded only to the north, and as the point where it joins the coast of Zanzibar. The extent of the coast-line exceeds 1500 miles.

The country extending along the sea is the only portion of Zanzibar which is known, and that only imperfectly, as it is not visited by European vessels. The description of other points to which slave-vessels formerly resorted, especially from the island of Bourbon, the interior is entirely unknown, and occupied by native tribes, which are always at war with the inhabitants of the coast, who are mostly trade and were called by

ZANCHI, a family of Bergamo in Lombardy, which produced several men of learning in the 16th century. Paolo Zanchi is considered its most distinguished member, a humanist, and a collector of ancient inscriptions. Three of his sons, Basilio, Gian Grisostomo, and Dionigi, entered the order of the Regular Canons of the Lateran.

BASILIO ZANCHI, born in 1501, went to Rome under Leo X, and is rarely visited by Englishmen of the Latin poet. After Leo's death he returned to Bergamo, and applied himself to theological studies, and entered the order of the Regular Canons in 1524. He wrote comments on the Bible, which are published. He was also well versed in Greek, and was employed by his Order of the Greek

and was suddenly converted to Huguenot, a Quaker, and an enthusiast in the order of the Regular Canons of the Lateran. basilio zanchi, born in 1501, went to Rome under Leo X, and is rarely visited by Englishmen of the Latin poet. length apart. The islands themselves seldom rise above twelve feet, and generally overhang the rocky flats on which they stand. The summit of the heights is level, and from the constantly depopulated soil it presents the surface of sharp points, over which it is difficult to pass. The country opposite this labyrinth of islands is a succession of hills covered with verdure and of well-rounded lowlands. The pasture contains many antiquities, consisting of moulting tombs, tottering cedars, and other ruins, which were doubtless erected before the Portuguese got possession of this country. Though the soil of this tract is apparently fertile and the climate healthy, it is very little cultivated, having been laid waste by the Gallars who have extirpated the former inhabitants, or obliged them to take refuge in the islands.

At the southern extremity of this region (near 2° S. lat.) begins a low coast-line, which however contains many excellent harbours, as those of Kwanzo, Patts, Lamou, Formosa, Melinda (Maleauda), and Mombasa. There are only a few coral islands along it. The shores of the bays and harbours are low and mostly swampy; they are overgrown with mangroves, but at a short distance inland the country rises into low hills, between which are wooded levels of moderate extent. The surface presents a soil varying from red to a dark black, which appears to possess a considerable degree of fertility. In Formosa Bay is the mouth of a deep river, which is wide at the sandbank, although deep inside and a large river, it is difficult of access on account of a dangerous quicksand, over which at low tide there is only four feet of water. According to the statement of the natives, this river rises greater than many of the rainy season inundates the surrounding country for many miles, destroying innumerable wild animals, among the rest many elephants. At the distance of fifteen days' journey in a canoe there is said to be a large town, Zookabey, beyond which the current is too strong for progress.

South of Mombasa the general appearance of the coast is low, but not swampy, and well defined, having a sandy shore, and in some places a small intervening strip of coral. But at some distance appear various insulated mountainous islands of various size, which present a remarkable contrast to the general flatness of the country. Except in one part, where the coast is a patrid marsh, the shores are lined with villages, rendered conspicuous by a grove of cacao-nut trees, in the midst of which they are built. The country is apparently fertile. Parallel to the shores, at the distance of four or five miles, there is a line of sand and coral reefs with deep water between and inside, but to seaward entirely uninhabitable. The bay of Lindy has a flat shore, which is formed by the silt from the alluvial deposits thrown down by the river Lindy, which appears to be large, and at a distance of about eight miles from its mouth branches into several small channels, forming a complete archipelago of low swampy islets covered with mangroves. A few miles further south is the bay of Monfunf, which, from its almost inaccessibility, which it discharges, is considered as the most considerable river, next to the Zambezi, on the eastern side of Africa, but we know nothing of its course.

Opposite this country are the largest islands along the eastern coast of Africa, the islands Pemba, Zanzibar, and Mombasa. The most northern is Pemba, known by the Arabs as Al Huthum, or the Green Island, which extends from north to south thirty miles, and from east to west ten. It is seven miles from the main at the north end, and twenty-five from Zanzibar. It is in any part not more than 200 feet above the sea, and rests on a coral foundation. It is one of the most fertile spots in the world, being covered with a very productive soil, from which luxuriant vegetation springs up and which it abundantly yields ship-timber: but the largest part of the surface is cultivated, and produces, besides other plants, rice of the finest quality: it is in fact the granary of the neighbouring coast. Along its western side from Tondong to its extreme extremity there are several profound and safe harbours, among which is the best that is Masal at Cheek-Chack. Zanzibar is nearly twice the size of Pemba, and resembles this island in soil and fertility. Besides every kind of grain which grows between the tropics, it produces great quants of sugar, which in quantity and quality, in respect to the Red Sea, and Egypt, there are numerous harbours between Zanzibar and the main, formed by the islands and reefs which are dispersed over the channel which separates it from the continent, and which is from five to ten miles wide. These harbours are safe, and not difficult of access; but within the shores of Zanzibar there is not one land-locked port, and in this particular this island does resemble Pemba. The numerous inhabitants carry on a branch of manufacturing industry to a considerable extent, that of making round shields, about a foot and a half in diameter. These are made by the soldiers of Imam of Muskat as a protection against the fire of musquetery. They are manufactured from rhinoceros horn, which after being soaked or boiled are easily moulded in any form, and then embalmed by burning. Modern ivory is very little valued, having been for some time past less esteemed than the old, which are studded with rhinoceros teeth and several islets, which render access to it difficult if it seems to be somewhat smaller than Pemba. It is abruptly from an unfathomable depth, and is based upon coral foundation. The surface is covered with trees, and it appears to be tenely well peopled. The channels between the island and the main is about twelve across, but so thickly studded with coral shoals as impassable for vessels of any size without considerable danger.

Near opposite the mouth of the Mozambique River are Quirimba Islands, a numerous archipelago. They are various sizes, but all low, and formed of coral greens, with long flat reeds extending seaward, and these abrupts from an immense system of flats of these islands and the main are excellent, being sheltered on the west by the mainland, and in every other direction by islands and reefs: they afford perfect security to vessels in the heaviest gales.

The climate in summer is between the dry and rainy season. The rainy season generally commences four or six weeks after the sun has passed the zenith, and as Zanzibar tends on both sides of the equator, it commences at different times in different places. The rains are extremely abundant, and the rivers sweep off the adjacent countries to the distance of several miles. The summer in very great, but as during the last even a half no European has resided there for any length of time, no meteorological observations have been made and it is however difficult to state that Zanzibar is cooler in the summer months to Europeans, even where the country is not hot or swampy.

The productions are various, but very imperfectly known. There are in general cultivated the same articles of commerce. Rice and melon ap{T} appear to be only two kind of grain which are grown. Dhol (a small species of pana), peas, and beans are the most common domestic plants. Musk-melons, pumpkins, and the sweet sugar-cane are grown: cotton, tobacco, and cotton-seed are also cultivated. The forests contain many large trees, which some are used as timber. A plant which produces caoutchouc is frequently met with. Horses are not frequent, and rather small. Asses are of good size. Horses are also in great supply. The sheep are of the Tartar breed: they are very small, but their fleece is delicate and sweet. A few goats are kept for their milk, which are very abundant. The larger wild animals in the interior are the elephant, rhinoceros, lion, leopard, and some kinds of antelopes. The rivers contain hippopotami, crocodiles, which are numerous south of the equator, but rare north of it. Fish are abundant, and many land subsist on the produce of their fishing. A kind of boiled salted or dried, is an article of commerce. The islands export a considerable quantity of palm-kernels in great quantities, and exported to Hindustan. Gold is brought into the interior, but not in large quantities.

Zanzibar is partly subject to native paramount and partly to the Imam of Muskat. Many of the Zanzibar inhabitants are Somalil, and their chiefs appear to be independent. From the river Zuba to the bay of Kanyo the Gallare have advanced to the shores of the sea, and keep possession of that tract. The country between the Zanzibar and Melinda is sparsely inhabited. From Melinda to the river Panyangi extend the territories of the Sheik of Sultan of Mombasa, which in 1823 were under the protection of Great Britain. The remainder of the coast, as far south as Cape Delgado, is subject to the Sultan of Zanzibar.

The inhabitants are either tribes of African origin or settlers from other parts of the world. The Arabic tribes are the Somali, Gall, Dowl, Wanyek, and Sultans.
The Somalis occupy the most eastern portions of Africa, and have their chief depots in the Bay of Aden. They have two principal towns, one on the Bay of Aden, and the other at a distance of more than 500 miles southward, on the west coast of the continent.

The town of Aden is the principal city of the Somalis, and is considered as their capital. It is situated on the east side of the Bay of Aden, and is surrounded by high mountains on three sides, and by the sea on the fourth. The town is built on a rocky height, and consists of a number of large and small houses, built close together, and surrounded by a wall of stone.

The town of Aden is of great importance, as it is the chief market of the Somalis, and is the place where they obtain their provisions, cloths, and other articles of trade. It is also the place where they are accustomed to meet and converse with each other.

The Somalis are a warlike people, and are noted for their courage and bravery. They are also noted for their skill in the use of the bow and arrow, and are able to shoot with great accuracy.

To the sixteenth century, they certainly were in possession of numerous points of the coast. Most of the castles which are still found there, though partly deserted, or abandoned to the attack of being wrecked by the Portuguese. The most northern place occupied by them was the promontory of Hafoon, on the coast of Ajan, near 10° N. lat., which they intended to convert into an island by a canal cut through the isthmus which connects it with the mainland, in order to make it more defensible. But having lost Muskat, and being pursued by the Arabs, they abandoned the enterprise, and soon began to lose one place after another, so that towards the end of the sixteenth century there was no longer a single point on this coast. The circumstances which brought about these changes are not known in Europe. After the Portuguese left the country, the Arabs of Muskat several times tried to occupy this coast, and more than once they succeeded in getting possession of some of its harbours, which however they generally lost after some time. It does not appear that they ever had in their possession so considerable a portion of it as at present, embarking all the same among Khyoo Bay to Cape Delgado, and the islands lying opposite this coast, with the exception of the territory of the Sheik of Mombas, who in 1823 placed them under the protection of the English, as already stated. (Narrative of Voyages to explore the Shores of Africa, Asia, and Madagascars, under the direction of Captain Owe).

ZANNICHELLA, a genus of plants belonging to the natural order Niaudaceae. This name was given by Micheli in honour of John Jerome Zannichelli, a physician and botanist, who was born at Nocera, in 1622. He had published a work on the preparation of medicines, entitled "Promptuarium Medicorum Chymicorum." He made many excursions through all the states of Venice in the capacity of physician-naturalist, an office to which he was nominated by the Senate on the occasion of an extensive museum of natural history, and died in 1729. After his death his son published various papers on botany, geology, &c., under the title of "Opuscula Botanica posthuma."

The flowers in this genus are monococcous. The male flowers have neither calyx nor corolla, with a single elongated filament surmounted by an oblong anther; the female flowers have a calyx consisting of a single leaf, no corolla, two green or four, the stigmas peltate, and the capsules sessile.

There is but one species of this genus, the Z. palustris, the Marsh Horned-Pondweed. It is a native of ponds, ditches, and rivulets in most parts of Europe. It also occurs near the sea coast in the countries of Southern Russia, and in the vicinity of the lakes of Lake and Rus. Koch, in his "Flora Germanica," records three varieties, major, repens, stipitata. These have been recorded as species by other writers.

ZANONIA, a genus of plants belonging to the natural order Marnionaceae. This name was given by Bontia in honour of James Zanoni, who was superintendent of the Botanical Garden at Bologna, during the 17th century. He published, in 1675, a folio volume in Italian, entitled "Istoria Botanica," containing descriptions and plates of eighty new and rare plants. He died in 1676. An edition of his works was published by Monti, in Latin, in 1742.

The only species belonging to this genus is Z. indica, the climbing Indian Cucumber. The fruit is described by Rhinanthus, only triangular, and having the flavour of the cucumber.

ZANOTTI, GIAMPIETRO CAVAZZONI, distinguished alike for his paintings and his writings, was born in Padua in 1702, and was a pupil of the school of Lorenzo Passini, and was the first painter of that city. Zanotti soon displayed great talent, and there are still several fine works by him at Bologna, in public and private buildings. He is however better known for his writings upon art, and few, says Lanzi, ever handled pencil and pencl so well as Zanotti. He published several poems, but the following are his principal works.

2. Life of L. Passini—Nuovo Fregio di Gloria a Felisima sempre pittrice nella Vita di Lorenzo Passini, Prince of Bolognese, Bologna, 1708, 4to.

4. hints to a Young Painter—Avvertimento per la formazione di un Giovane alla Pittura, Bologna, 1728.

He wrote also a Life of Bologna, and whole volumes of poems by him were published at different periods in Bologna. He was secretary to the Institute of Bologna, in which his brother F. M. Zanotti held the chief of philosophy. His writings are of a philological history of the Academy Clementia. He died at Bologna in 1755, aged 91, and was buried in the church of Maria Maddalena, where there is a monument to his memory, with an inscription beginning as follows:—

Zenotti, Academia Clementina, &c.; Fasani, ann. Bolognus,

ZANTE (Zanesia, or Byzantium), one of the present Ionian Islands. The chief town, of the same name as the island, is situated between 37° 32' N. lat. and 23° 13' E. long. The nearest headlands of the More (now Niccolo), and of Zante (the point of Domia), are 2 English miles asunder.

From Cape Skinari, the most northerly part of the island, to Cape Gerakia, a stone-bastioned fort in a straight line 23 English miles in the direction north-west to south-east; from Cape Skinari to Kieri, the south-west head, is 22 miles in the direction north to east of south. Cape Gerakia and Kieri are headlands of the south coast of the Gulf of Gerakia, an extensive marine museum, and the border of the Gulf of Ionian, 8 English miles. A particular drawn from a straight line joining these points, the boundary of the Gulf of More (point of Domia), is 2 English miles asunder. The north-east coast is indented by two deep bays. The bay of Zante and the Saline cuts into the south of the straight line joining the extreme part of this coast; and the headlands of Xanthi (south of Zante) and Knyrono (north of it) advance about to the north of Mount Vrachion (324 feet), near the headland of Mount Vrachion (254 feet), which cuts into the south-west angle of this plain, near the shore of the bay of the Gulf of Kieri, the pitch-wells mentioned by Herodotus.

The only sheltered ports in the island are the Gulf of Kieri. Between the main and the small isle of Polis and Marathousa, but the mouth of the river Bousa renders them unavailable for the purposes of commerce. The bay in which the town of Zante is situated is a small open roadstead. The Camura, the only navigable river of the island, falls into this bay. The bay to the north-west of Zante, on the nearest part of which are situated the Salines of Calistri, is full of shallows, and has at its entrance the reef of St. Nicola.
Though there is only one stream of water in the island, there are plenty of springs. Some of them are hot, and those, along with the pitch-wells, would of themselves indicate that subvolcanic formation which the frequent and violent earthquakes to which Zante is liable would lead us to attribute to it. The climate is agreeable. The epithet 'woody' (άλησις, 'mimosaros'), bestowed upon it by Homer and Virgil, is no longer applicable, the only wood on the island being a species of poplar. The principal article of export is, however, the olive, which is principally grown on the lime trees on the greater part of the island in the interstices of the olives, and that of an indifferent quality. Some wine is made, of which nearly half the island is sufficient to supply the inhabitants for three months of the year: the supplies for the other nine months are derived from the Morea. The mineral products are bitumen, of which 100 tons are annually extracted from the island, and salt, of which any quantity might be manufactured, though the inhabitants make little more than serves to salt their olive oil.

The pitch-springs of Zante were visited by Herodotus in the fifth century B.C., and described by him (iv. 195). The pitch was then collected for economic purposes. Thus we have evidence of this supply of pitch having existed two thousand years ago, and it is probable that it has not been interrupted. Pliny describes it (xxxv. 15).

There are some inconsiderable manufactories of cloths, silks, and cotton thread, jewellery, liqueurs, and soap.

The population of the island was estimated, in 1863, at 40,000; of these 10,000 inhabited the town of Zante, the rest being in small villages. The rest are contained in 45 villages. Under the jurisdiction of the local governor of Zante are placed all the smaller islands around it, and along the shore of the Morea from Zante as far south as Cape Gallo.

Zante is the ancient Zaeinthus. According to Pausanias, Zaeinthus, the son of Dardanus, of Phoebus of Arcadia, colonized the island; Pausanias mentions this tradition by way of explaining the fact of the acropolis of Zanzibar being called Phoebus (vii. 24). This legend, and the tradition attributed to Boeotius by Pliny (xxvi. 79, ed. Hard.), that Saguntum in Spain was founded by emigrants from Zaeinthus two hundred years before the Trojan war, implies that it was early distinguished among the Greek islands. (Livy, xxxvii. 17) and Strabo (p. 159, ed. Cassub.) also make Zaeinthus the parent city of Saguntum. The Zaeinthians themselves were a colony of Achaenians from the Peloponnesus. In the Peloponnesian war Zaeinthus sided with Athens and was ravaged by the Laconians. (Thucyd., i. 66.) The Zaeinthians also joined the Athenians in the invasion of Sicily. (Thucyd., vii. 57.) The island remained independent till the war of the Romans against Perseus, in which its inhabitants embraced the Macedonian party. At the termination of the war it was declared a dependency of Rome, and placed under the praetor of Asia. The island continued an integral part of the Roman dominions, and, after the partition of the empire, of the Eastern empire, till its subversion by the Turks. In 1498 Zante was taken by the Venetians from the Turks, but restored at the peace of 1501. In 1578, having again fallen into the hands of the Venetians, it was ravaged by the Turks. Since that period it has constantly remained one of the Greek dependencies of Venice, and has passed, with the other islands of the Ionian group, from Venice to France, and from France to England. [IONIAN ISLANDS.]

(ZANTHOMIZA. Mr. Skennard's name for a subgenus of Meliphaga. [MELIPHAGI.] The proper form is ZANTHOMYZA.)

**ZANTHOMYZA.**

Generic Character.—Bill moderate, much curved; the casque considerably elevated. Face naked. Middle toe much longer than the hallux. The femoral tarsal (type. Soc.)

Example, Zanthomyza phrygana.

Description.—Nares nearly alike in colouring, but the female much smaller than the male. The young de-tritus is white, but soon excretes from the face, that part being wholly clothed with feathers.

Head, neck, upper part of the back, chin and chest, black; scapulars black, broadly margined with pale yellow; lower part of the back black, margined with yellowish white; upper tail-coverts like the scapulars; wings black, the coverts margined with yellow; spinous wing yellow; primaries black, with an oblong stripe of yellow occupying the margin of the outer and a portion of the inner web next the quill, which is black; secondaries black, broadly margined on the outer web with yellow; under surface black, with an arrow-shaped mark of yellowish white near the extremity of each feather; two centre tail-feathers black, slightly tipped with yellow; the remainder black at the base, and yellow for the remainder of their length, the black decreasing and the yellow increasing as their position proceeds from the outer to the central ones; sides reddish brown; bill black; feet blackish brown; warty excrescences covering the face dirty yellowish white. (Gould.)

This is the *Myops phrygana, Black-and-yellow Bee-eater and Black-and-yellow Honey-eater of Linnaus; Embroidered Bee-eater of Shaw; Warty-faced Honey-eater and Meliphaga phrygana of Lewin; Le Mele Geoffroy de Le Vaillant; Philemon phrygana of Vieillot; Anthocharis phrygana of Vigors and Horsfield; and Most Regent Bird of the colonists of New South Wales.

Geographical Distribution. Habits, Food, &c.—Mr. Gould, who has collected the synonyms above noticed, states, in his great work on *The Birds of Australia* now in the course of publication, that this is not only one of the handsomest of the Honey-eaters, but is also one of the most beautiful birds inhabiting Australia, the strongly contrasted tints of its black and yellow plumage rendering it a most conspicuous and pleasing object, particularly during flight.
Although it is very generally distributed, its presence appeared to Mr. Gould to be dependent upon the state of the *Eucalyptus* [EUCALYPTUS], upon whose blossoms the bird mainly depends for subsistence; and it is, consequently, only to be found in any particular locality during the season when those trees are in full bloom. 'It generally resorts,' says Mr. Gould in continuation, 'to the loveliest and most fully-flowered trees, where it frequently reigns supreme, buffeting and driving every other bird away from its immediate neighbourhood; it is in fact the most pugnacious of the bird species, and in particular hinders the smaller Meliphagides, and even to others of its own species that may venture to approach the trees upon which two or three have taken their station. While at Adelaide, in South Australia, I observed two pairs that had possessed the same tree; but it appeared to me that the smaller trees that had been lost standing in the middle of the city, which tree, during the whole period of my stay, they kept sole possession of, rallying forth and beating off every bird that came near, I met with it in great abundance among the bushes of New South Wales, and also found it breeding in the low apple-tree flats of the Upper Hunter. I have occasionally seen flocks of from fifty to a hundred in number passing from tree to tree, as if engaged in a partial migration from one county to another, probably in search of a more abundant supply of food.'

The same enterprising observer states that the note of this species is a peculiar loud whistle not entirely devoid of harmony, and describes the nest, which is usually composed of overhanging branches of a *Eucalyptus*, round, cup-shaped, about five inches in diameter, composed of fine grasses, and lined with a little wool and hair. The eggs are two in number, of a deep yellowish buff, marked all over with indistinct spots and irregular blotches of a lighter and dull purplish grey, particularly at the larger end, where they frequently form a zone.

The stomachs and intestines of the specimens which Mr. Gould killed and dissected among the brushes of the Billabong, is entirely filled with liquid honey only; insects however, he thinks, doubtless form a considerable portion of their diet.

**ZAPORZIA, Dr. Leach's name for a genus of RALLIDE.**

**Genetic Character.**—Bartment slender, shorter than the beak; the bill long, compressed, acute; upper mandible gradually incurved. *Nestris* linear, lateral, placed at the base of the bank. *Leva* long, slender, obtus, with three toes in front; the hinder toe elevated from the ground at its base; the tibia half naked. (Gould.)

**Example.**—Zaporzia porzana, Spotted Crane.

**Description.**—Adult and Old Male. Forehead, eyebrows, and throat, leaden grey; sides of the head, ash marked with black; upper parts olive brown, but all the feathers black in the centre and variegated with small spots and stripes of pure white. Breast and lower parts olive green, with ash and marked with white spots; these spots are rounded on the breast, but disposed on the sides in transverse bands. Middle tail-feathers bordered with white; lower tail-feathers pure white; Bill greenish yellow, red at the base. Feet greenish yellow. Iris brown. Length about nine inches.

**Adult Female.**—Ash-colour of the throat and neck less extensive; sides of the head with brown spots; base of the bill with less reddish. N.B. Both sexes, in autumn, have the bill of an olive green, brown at the point.

**Young when first hatched.**—Covered with black down. Young before the Molt.—Throat and middle of the body whitish ash, often whitish with small brown streaks. Eyebrows, face, and cheeks dotted with white and black. On the lower parts a greater number of white spots than in the adults. Lower tail-feathers bright rusty. Bill and feet greenish brown.

**Geographical Distribution.**—Sweden (summer visitor, rare). Southern Russia, North of Germany and Holland (rare). France, Provence, and to the Mediterranean (more common). Of most frequent occurrence in the South and East of Europe. Has been seen at Smyrna in the winter, and is stated to extend to India, England, Scotland, Wales (summer visitor, but not common). Ireland (occasional summer visitor).

This is the *Petit Râle* of Eur. Davidcoulomme and *Marabout de l'Europe* of the French; *Porzana* of the Germans; *Porzana* (Porzana) *Grauendio*, *Grazendio*, and *Gallinella* of the Italians; *Punktierlsvolkhu* and *Kleine gesprekelte Wasserhühner* of the Germans; *Speckled Water Hen* and *Shitty* of the modern lyric, and *Dusky Crake* of the ancient Britons.

**Habits, Food, &c.**—Slugs and other small molluscs, worms, water-insects, and tender vegetables form the food of the Spotted Crane, which arrives in this country about the middle of March, and stays as late as nearly the end of October. In those countries (marine principal) where it seeks congenial haunts in marshes or morasses, the sportsman finds a good dog necessary to force it from reeds, rushes, or tangled rank grass which hinder the gun or slug-gish stream. Colonel Hawker gives the best directions for managing them in the field, and, as in most of the other valuable hints, in a few words. 'In shooting all long rails, press them very hard, or you will have difficulty in getting them on wing. If they are in a hedge, go near your dog's, and shake it before them. Having done this, you should fire, if there is any chance, as the difficulty of springing them a second time is tenfold.'

Although the Spotted Crane is not common in the islands, there is no doubt that it breeds here, the eggs of young having been found in the Norfolk marshes and other localities. Mr. Selby, accompanied by a shooting dog that was up to its tricks, sometimes flushed as many as six in the large Northumbrian moors in his neighbourhood, just before their autumnal migration, and these were young birds of the year.

The nest is generally formed in some reedy or wooded marsh on the sandy soil, and often on the bank opposite to the pool on which the particular species of *Eucalyptus*, or water-plants, are inhabited. It is composed of a finer lining

The six, seven, eight, or ten reddish white eggs are spotted and speckled with dark rusty brown, and, as soon as the young Crakes quit the shell, Montagu says that they become whitish, or else grey, and are regarded by sportsmen, yet there is scarcely a greater delicacy than the one or the other. Both are indeed first-rate, but the Spotted Crane for choice.

There are two other European and British Zoop. viz. the Little Crane or Ostragesus Gallinula, Zeyp-putza, and Ballain's Crane, Zaporzia ballainn, of which the late Mr. Temminck says that the sprees are often found in Japan are the same with those killed in Europe.
Two species, Zopornia notata, Gould, and Zopornia splendens, Gould, are figured and described in 'The Zoology of the Voyage of H.M.S. Beagle,' edited and superintended by Charles Darwin, Esq.

The habitat of the first of these, which was shot on board the Beagle, is stated to be the Rio plata; of the second, the Galapagos Archipelago.

The following is Mr. Mark's description of the habits and locality of the last-mentioned species:—This bird frequents in large numbers the high and damp summits of the islands. It lives in the thick beds of Carex and other plants, which, from the condensed vapour of the clouds, resemble a forest. The bird is in this instance concealed; it often utters a sound and peculiar cry. The female is said to lay from eight to twelve eggs. It is, I believe, the only bird in this archipelago which is exclusivly confined to the upper parts of the islands.

ZARA, one of the four cities of Audressel-Dalmatia, is composed of the northern portion of the continental part of the province, of the Quarnero islands Arbe and Pawe, and of some adjacent islets. Its area is 2000 square miles, with 125,000 inhabitants, of whom about 88,000 are Roman Catholics, the rest a Fremunder Not United (i.e. Schismatic) Greeks.

ZARA, the capital of the circle and the kingdom, situated in 44° 8' N. lat. and 15° 15' E. long., lies in the plain between the hills of which it is divided from the continent by a deep moat, over which there is a drawbridge. The city is divided by a straight main street and a cross street into four quarters; the other streets are straight, but narrow, ill paved, and unfrequented. The origin of the name is uncertain. It is derived from (borgo intorno e erizzo, or Albanian village), 650 stone houses and 8000 inhabitants, most of whom speak Italian. Of the six churches (in which there are many good paintings) the most worthy of notice are the San Giusto, called Ducale, by the Venetians, and that of St. Simeon, the patron saint of the city, whose mortal remains are deposited in it. Zara is strongly fortified; the harbour is excellent, and capable of containing a large fleet. It is the seat of the government of the province, has great maritime offices; the residence of a Roman Catholic archbishop, and its chapter. Among the public institutions and establishments are a lyceum, a gymnium, an archiepiscopal seminary, a normal high school, a public school for females, a college for land and civil and military hospital, a naval and military arsenal, a theatre, a casino, &c.; the Pellegrini Museum is a private collection of works of art and antiquities. There are two great canals which form the commercial channel. The city is a great fishery, especially that called Marschello. Most of the inhabitants however derive their subsistence from the fishery amongst the neighbouring rocky islets (scogliere), on several of which a little flax is grown. The trade of the city is exceedingly large; it is the central part of a group of subordinate cities; the residence of a Roman Catholic archbishop, and its chapter. Among the public institutions and establishments are a lyceum, a gymnium, a normal high school, a public school for females, a college for land and sea officers, a naval and military hospital, a naval and military arsenal, a theatre, a casino, &c.; the Pellegrini Museum is a private collection of works of art and antiquities. There are two great canals which form the commercial channel. The city is a great fishery, especially that called Marschello. Most of the inhabitants however derive their subsistence from the fishery amongst the neighbouring rocky islets (scogliere), on several of which a little flax is grown. The trade of the city is exceedingly large; it is the central part of a group of subordinate cities.

A very great inconvenience is the want of sufficiency of fresh water, which is felt almost every year during the heat of summer, notwithstanding the four springs which contain 40,000 tons of water. On some occasions, for instance in 1828, the inhabitants have been obliged to obtain a supply from the waterfalls of the Kerta, nearly 50 miles distant.

ZARINA. [Soudan.]

ZARLINO, GIOSEFFO, the most celebrated of all the Italian writers on the speculative and practical theory of music, was born at Rapallo, February 7th, 1517, in the city of Rapallo, in the province of Genua, of what ever age or country, who have treated on this subject, Meisene and Kircher excepted,—was born at Chioggia, an episcopal city in the Venetian States, in 1519, and little more is known of his parentage by history. Judging from his education and mathematical knowledge, it would appear that, though entered as a boy-chorister at St. Mark's, Venice, he was educated for one of the learned professions, and the reverendo prefixed to his name, which seems to have been a usual title, indicates that he was of the ecclesiastical order. It is stated by Sir John Hawkins, as an established fact, though he does not name his authority, that Willard, his master in the cathedral, prevailed on him to devote himself chiefly to music, which information he most likely found in Salinas. He is styled, in the best edition of his works, that of 1591, Trattato di Cappella de 1' Arcivescovi Sigurgio de Venetia; or, in other words, he was director of the music and organist of the state church, St. Mark's, at Venice, in which office he succeeded Willard. Boyle therefore, in his translation of this title, is not in error, as Hawkins alleges, who possibly may not have examined the original with his usual attention.

Zarlino published his first work, L'istitutioni Harmoniche, in 1554, from which period Dr. Burney tells us (who has been an uncorrected in his dates, he was continually revising and augmenting his works.) The same author further remarks, that the musical science (i.e. its practical part) of Zarlino may be traced in a right line from the Netherlandis, as his master, Willard, the founder of the Venetian school, was a disciple of John Dethon, who was a scholar of the great Josquin. [Willard.]

The works of Zarlino, in the edition before mentioned, are in four volumes or parts (quattro volumi), bound up in three thick folios, of which upwards of a thousand pages are devoted to music, and all the forty to the essays. Their titles are 1. L'istitutioni Harmoniche, divided into four parts. 2. Le Demonstrationi Harmoniche, contained in five dialogues. 3. I Supplementi Musicali, in eight books. 4. Un Trattato di Patience, or of Patience on Patience, most useful to such as would lead a Christian life. Un Discorso, &c.: A Discourse on the true year and day of the death of Jesus Christ. Un' Informazione delle origini dei R. P. Capuccini: Information relative to the Capuchins in the院校 of d'acolti Dubij, &c.: All doubts removed concerning the correction of the Julian year, as made by Pope Gregory XIII.

It is evident that Zarlino supplied all subsequent writers on the subject of ancient music with many valuable materials. He was most laborious and indefatigable in his researches, and successful in their results. But it must be admitted that he was obstinate of his learning, and might have compassed his three first volumes into half the space, with great advantage to himself. His prolixity has, no doubt, deterred many from proceeding far with him; nevertheless, an experienced person, one who knows how to make the use of a well-informed and terse and tedious writer, will not regret having looked through, and occasionally studied, the works of Zarlino.

ZEZ (called Kise) by the Greeks, Cea by the Romans, an island in the Egean, about 13 English miles south-east of Cape Colonna: the island of Makronisi is nearly in the middle of the island of Cea, is inhabited, and contains about 5700 N. lat. and 24° 20' E. long., on the southern coast of the island of Mount St. Elias. The island is 14 English miles in length from north to south, and 10 in breadth from east to west. It is one broad-tailed hill rising from the low shore-line to the height of Mount St. Elias. The island is said to contain 'the shore,' says Mr. Addison, 'made us hope for more than the usual cultivation, but we were disappointed. There is only one miserable town built on a mountain. There are some remains of the ancient Cills to be seen, consisting chiefly of the ruins of a temple. Most of the Egean islands, which are so beautiful at a distant, are nothing but bare, scraggy, uninhabited rocks.' Notwithstanding this dismal description, the capital, which is situated on the brink of a ravine between 2 and 3 miles inland from its port, Raphilimani, is inhabited and contains about 8000 inhabitants; and the whole island about 5000. The climate is healthy. The products are barley, fruits, tolerable wine, cotton, sheep, and silk-worms. Zea is the ancient Cittos, but it does not appear that any temple was ever built beyond the temple mentioned by Addison, and the ancient walls of the capital. A survey of this island has been executed by direction of the British Board of Admiralty, but the plan has not been executed, nor the materials so arranged as to be accessible.

Strabo (486, ed. Camb.) states that Cittos had originally four cities, of which only Cittos and Carthara existed in his time: Poessa had been united with Cittos, and Cittos and Carthara united for the sake of Julius. Stephanus (sive, in the title, or by the error of copyists, calls Carthara a town of Zara, Simonides was a native of Cittos, and also the poet Barchides, Erastinus the physician, and Aristotle the Peripat-
the philosopher. The people of Cæs were Ionians from Athens, and they supplied seven vessels to the Greek fleet at the battle of Salamis, B.C. 480.

( C. G. Addison, A Journey to the East ; Arrowmith's Map of Greece; Dictionnaire Géographique Universel.)

ZEA, a genus of plants belonging to the natural order Gramineae. This name is identical with the Greek Zeéa, but the Greek plant was a species of Triticeum or Hordeum, and not at all agreeing with the present genus, which is entirely American.

The species belonging to this genus are monocious. The male flowers are in distinct spikes: the eilaxis consists of a 2-flowered blate glume; the corolla of a blate glume: in the female flowers the eilaxis is a 2-valved glume; also the corolla; the style is single, efform, pubescent; the seeds solitary, immersed in an obovate receptacle. There are two species.

Z. Mays, Common Maize, or Indian Corn, which is known by its entire leaves. It is a native of America, and is cultivated there, as well as in most countries of Southern Europe. It is the species Triticeum, those of this genus present almost innumerable varieties, from the cultivation to which they have been submitted. As an article of food, the sugar is much inferior to that of the Triticeum, nor will it ripen fully in high northern latitudes.

Z. Caragana, Chili Maize, or Valparaiso Corn, is distinguished by its serrated leaves. It is a smaller plant in all its parts than the foregoing, and is a native of Chili. A sort of religious reputation is attached to this plant on account of the grains when roasted splitting in the form of a cross.

A new application of the maize has been lately proposed. It is found that previous to the ripening of the fruit the sap of the maize contains a large quantity of sugar. If this sap be boiled and the sugar may be easily obtained from it, and in such quantities, it is stated, as would render the cultivation of the maize for this purpose much more profitable than that of the sugar-cane. Professor Croft, in a paper read at the Linnean Society, in February last, stated that experiments had been made on this subject in India, from which it appears that the sap of the stalks of the maize contains more than three times as much sugar as that of the beet, and five times as much as that of the maple, and frequently exceeding in quantity that of the ordinary sugar-cane as grown in the United States. The preparation of the sugar is also stated to be much more easy than that obtained from the sugar-cane. Another advantage also is the fact, as the juice in which the maize comes to perfection, as the juice may be obtained from seventy to ninety days after the planting, whilst with the sugar-cane it requires eighteen months. The refuse from the stalks is found to make an excellent fodder for cattle. The quantity of the sugar is said to be increased by destroying the ears of the corn during its growth.

(Cyclopedia of Plants; Reports of Linnean Society, in Gardener's Chronicle.)

ZEA MAYE. [Maize]

ZEA, or May, is a province of the kingdom of the Netherlands, situated between 54° 14' and 51° 47' N. Lat. and 3° 13' and 4° 7' E. Long. It is formed of the ancient province of that name, of the tract called Dutch Flanders, and of a group of islands formed by the several arms of the Scheld. It is divided into five parts, which are the north by two, the centre of which is the Scheld, which separate it from the islands of Overflade and Goeree, belonging to the province of Holland; on the east by the provinces of North Brabant and Antwerp; on the south by Flanders; and on the west by the German Ocean. Its area is 7866 square miles, and its population to the official return, was, on the Ist of January, 1812, 135,533 souls. The surface is low, only a few feet higher than the sea, and the monotonous plain is only broken here and there by artificial mounds, sufficiently protected by dews from the encroachments of the sea, it is necessary to secure the country by numerous dykes, which run along the coasts and the sides of the rivers; yet different parts of the province have been exposed at times to severe estaminities from the breaking of the dykes in storms at high tides, particularly in the years 1302, 1363, 1522, 1532, and 1548. Whole towns and districts have been overwhelmed and abandoned; and though parts of them have been subsequently recovered, several
Zealand, or SEELAND, is the largest and most important island of the Danish monarchy. It lies between 53° 2' and 56° 8' N. lat. The area is 7,362 square miles (according to other estimates only 6,040). It is bounded on the north by the Great Belt, on the west by the Sound, which separates it from Sweden; on the east by the Great Belt, which separates it from the island of Funen; and on the south by the Baltic, which separates it from the islands of Moen and Falster. The surface of this island resembles that of the mainland, having no mountains; but it is not, like them, a uniform flat; it is diversified with low hills, and contains many beautiful spots adorned with fine beech-forests, which present a variety of scenery, the appearance of which, when the air is clear and fine, is heightened by its perfection, that has been compared with that of Lombardy.

The soil is very rich; it yields abundant crops of corn, especially barley. The pastures too are excellent, and the herbage there is almost inexhaustible; the latter, though rich, is but spirited. In the middle of the island turf is used for fuel, wood not being so plentiful as in the other parts. The bays and creeks, with which the island is indentured on all sides, abound in fish of many different kinds. Most of the men, however, live by farming. Denmark is a confederacy, with the island of Zealand, the population of which is 400,000 souls. Zealand contains the capital, Copenhagen, the fortress of Holstein, which commands the entrance of the Sound, and all ships passing through that strait pay the Sound duty. Copenhagen, or Fligt, is composed of royal palaces and country-houses.

Denmark; Copenhagen; Elsinore.

The bishopric of Zealand, 3000 square miles in extent, with 300,000 inhabitants, includes, besides Zealand, the islands of Bornholm, Moen, Samsoe, Oesel, and some small islands in having no mountains; but it is not, like them, a uniform flat; it is diversified with low hills, and contains many beautiful spots adorned with fine beech-forests, which present a variety of scenery, the appearance of which, when the air is clear and fine, is heightened by its perfection, that has been compared with that of Lombardy.

The soil is very rich; it yields abundant crops of corn, especially barley. The pastures too are excellent, and the herbage there is almost inexhaustible; the latter, though rich, is but spirited. In the middle of the island turf is used for fuel, wood not being so plentiful as in the other parts. The bays and creeks, with which the island is indentured on all sides, abound in fish of many different kinds. Most of the men, however, live by farming. Denmark is a confederacy, with the island of Zealand, the population of which is 400,000 souls. beach. The natives have many plantations here, and they get good crops. Towards Cape Wara, where the isthmus joins the broader peninsula, the land is of great fertility. On the eastern shores of the isthmus is an isolated hill, called Mount Camel, or Houhoun, which rises 500 feet above the sea. On its southern side is a harbour capable of receiving the largest vessels, with anchorage close to the eastern shore; but the entrance is not more than a league wide. The southern extremity of the isthmus, Houhoun is partially cultivated. Where the isthmus terminates on the south there is an extensive alluvial district, which stretches from the western to the eastern coast, and for miles amount to the course of the Awaron, a river which empties itself into the estuary of Rangaunui. This tract is of great fertility, and, when cultivated, produces very abundant crops of wheat, Indian corn, and other grain. In its natural state it is perfectly open in many places, and only covered with Coriaria sarmosenta, fern, high flax, and here and there some spots of grass. In other parts it is overgrown with a jungle of Dracena australis. The estuary of Rangaunui is an extensive arm of the sea, but it is shallow, and the intricate channel admits only moderately-sized vessels. The Awaron, though a small river, is navigable for boats at high-water to the distance of about 10 miles; the tides rise 10 feet, and the river has little fall in its lower course. Canoes ascend it nearly to its source, which is at the foot of Maunga Taniva, a remarkable mountain, rising 1500 feet above the surrounding hills. The upper valley of the river is here and there clothed with groves of large trees. The whole valley of the Awaron contains about 120,000 acres of land. Within a short distance of the sea, due to the quality of the soil, the facility of cultivation, as well as of water-communication, the abundance of excellent wood and of other building materials, this tract is one of the most favoured in New Zealand. There are several European settlements. The Hills has more progress in civilization than in other parts of the islands; they cultivate, besides Indian corn and sweet potatoes, wheat, potatoes, vines, and various fruit-trees and vegetables; they also keep horses and cattle. They have mills which to the shores of the sea and for internal communication.

On the south of the valley of the Awaron extends a hilly region from sea to sea. Its upper surface is a continual alternation of descents and ascents, but the slopes are generally gentle. land side. The only exception to this general description is the valley of the Kawa-kawa, an arm of the sea stretching back about nine miles into the interior, which, though it is navigable for several miles from its mouth. This valley contains a considerable amount of excellent land, and is very extensively cultivated by the natives. In this bay is the sand island of Kororatuka and the projected islands of Russell and Victoria, Many Europeans are settled on the shores of this bay and in the valley of the Kawa-kawa.

Between Cape Brett on the east and Hokianga River on the west the island is about 60 miles wide. From this line the coastline widens several hundred miles, and, though it runs in a continuous line, not interrupted by any indentation. Along the shores is a beach from 100 to 150 yards wide, which is partly covered with soft sand and partly by large fragments of pudding-stone. At the back of it rise sandstone cliffs to the height of 300 feet, and a tract of land from four to six miles wide consists of sandhills covered with a carex, and farther inland with a scanty vegetation of fern. Among these hills, and close to the sea-shore, rises Mount Mangapui, an isolated mass which gives a certain security against the sea-coast storms of the sea. Farther inland the country is a table-land some hundred feet above the sea-level. The highest part of this region frequently extends in a level plain for several miles. This soil is generally arid, resembling the heath in England, though it contains many areal, which are covered by sea. In depth, and rests on tough argillaceous earth. It is overgrown with fern, and in many places with shrubs, especially elderberry bushes: there are however many tracks which are depressed below the surface of the plain, and these after the rains are converted into swamps, which are generally overgrown with the flax-plant, and traversed by deep and narrow gullies. Where the plains approach the river-valleys and decrease in height they are covered with forest, consisting of kauri, kahikatea, and the native pines of the valleys. These forests contain many large timber-trees, and in no part of the island is the kauri-pine so abundant or attains such a size as in this region. The natives are mostly employed in felling and squaring the timber. The bottoms of all the rivers are bounded by hills of great height, which do not generally reach to the banks, and are often more than a mile from them; the bottoms are level, and have a somewhat clayey but fertile soil, being mostly composed of the detritus brought down by the rivers. The bottoms rise little by little from the sea, and the formation of all descriptions, especially the kauri-pine, except the alluvial tracts of recent formation and those lands which have been cleared by the natives for cultivation. They raise all the common productions of the island in abundance, and are a surplus, which is sent to the market and added to the profits derived from the timber, renders them more wealthy than the native inhabitants of other districts.

Kai-para Harbour is a large basin. The entrance is between five and six miles wide. Before it is an extensive sand-bank, which runs to sea six or eight miles, and extends from north of the northern head to south of the southern head, so that it appears, when seen from the westward, to form an approach. This sand-bank, however, is but inside this bank there is a deep channel at least two miles broad in the narrowest part, which affords a safe passage for large vessels. The tide rises ten feet at full and change, and rushes with great violence into the harbour, while, as before mentioned, the western winds, which blow without intermission during some parts of the year, and increase the current which sets into the harbour, are also a great drawback from the utility of this harbour, as they prevent vessels from leaving it. The river of Waikawe requires about 15 miles of navigation on both sides. There are several small navigable streams which are numerous at which a vessel is protected from all winds. Besides several smaller streams, three large rivers fall into the bay, the Wairoa, Otamatea, and the Kai-para.

P. C., No. 1773.
which leads to Auckland. Waiteheke is about 30 miles in circumference, wooded and hilly, and contains kauri-trees; but it has also many sheltered and cultivable small valleys. It has a harbour for small vessels, and there is anchorage for larger vessels in the channel which separates the island from the mainland.

The chief of the valleys between Kai-para, on the west, and the northern part of the Shouraki Gulf, is nearly covered with hills or small table-lands overgrown with fern; but their declivities towards the gulf are covered with fine timber, which is exported from the harbour of Manu-ku, and adds to the annual revenue of the district. From the north-west, 20 miles from Waitemata Harbour, a valley runs to the north: which is easy of access, and has depth of water sufficient for every description of vessels, and there is secure anchorage. Though the land available for cultivation is not of great extent, it has lately been laid out on the shores of the harbour.

Some miles north of Waitemata Harbour the hills sink down, and the narrow part of the island, which is between this harbour and the Manukau Harbour on the western coast, has a slightly undulating surface, on which several isolated hills rise to some height. The soil is of good quality, and fit for all kinds of horticultural and agricultural purposes. The harbour of Waitemata, on the southern shores of which the capital of New Zealand, Auckland, is built, is the western extremity of the gulf, and also has its ramifications towards the harbour of Manukau. The navigable channel by which the harbour is entered is only three-quarters of a mile wide, being narrowed by a reef; but within the channel widens to an average breadth of a mile, and is deep enough for vessels of great burthen of fathoms in the channel, and three and three and a half at the sides. It extends ten miles to the westward, and branches off at its western extremity into two arms, of which the southern, running towards the harbour of Manukau, is a river-like inlet, but adds to the difficulty of navigation for vessels for part and the harbour of Manukau there is only a portage of one mile and a half. This inlet however is only navigable for boats. Near the harbour of Waitemata is that of Tamaki, at the innermost corner of which a portage of only a mile brings the boats to the beach of Manukau. At the entrance of the harbour is a bar, with six feet of water at low tide, but vessels of 200 tons can enter it, and large barges can go to the portage.

Where the Gulf of Shouraki grows narrow, opposite the island of Waiteheke, the country rises to a higher level, and presents towards the gulf a hilly ridge, in which several narrow valleys open to the estuary of the Waio; they have a fertile soil, and contain settlements of natives. This hilly ridge runs in a south-westward direction, where it separates the valley of the Waio and of the Waikato river, and is known as the Waikato river; but sinks lower as it proceeds towards the source of the Waio, or rather the general level of the country rises higher. Between the upper course of Waio and Waikato only isolated hills and valleys are dispersed over the table-land. This chain of hills is mostly covered with bush, of which, in the west, is the kauri-trees, and, in the north, of basalt, and wood is only found in some small mountains and ravines. There are kauri-trees, but they are rather scarce.

The valley of the river Waio, which lies to the east of this hilly range, and begins at the most southern branch of the Gulf of Shouraki, is the largest known plain in New Zealand. It extends about 60 miles south, terminating in the low hills of Horomoro, where the river Waio originates, and then extends north for about 20 miles from the mouth, but grows narrower as it runs southward, but probably in no part does it fall short of 10 miles in width. The surface is a dead level, and large tracts, especially towards the gulf, are converted into swamps for the want of necessary drainage. In these parts the soil is almost sterile, and the swamps are not offensive, though in the upper part of the valley, nor large, but they increase in number and extent towards the mouths of the rivers, where the country is very low and subject to inundations. In these parts the soil is sterile and rich, and the swamps might easily be drained. But they are filled by sand brought by the Plume River, which, in this part, is a series of sand-hills, and is not offensive.

The plains of the Waio and Whangaroa are extensive, and there is subject to inundations. In these parts the soil is sterile and rich, and the swamps might easily be drained. But they are filled by sand brought by the Plume River, which, in this part, is a series of sand-hills, and is not offensive.

The country extending along the western coast of the Manukau, as far as the river Mokau, appears to rise more gradually to a higher level than the northern districts of the island. The shores have in many places a low sand-bank, and in others they are also very low, where the sea washes the base of steep cliffs composed of sandstone and conglomerate. For some miles from the sea the country exhibits very few signs of fertility, being
mostly overrun by a carex, or a stunted vegetation of fern; few bushes or trees are met with, except in the numerous ravines, which have a fertile soil, and where there are a few large trees. A few miles from the sea the country rises higher, and contains numerous hills whose declivities are gradual, and partly covered with fern and flax, and partly wooded. The soil of this tract is rather fertile, especially where it is loamy or the mould rests on limestone; and in many parts there are plantations.

The navigable carex, and about stunted a lat.) But hilly it is joined has is increased: in inland anchorage Kawia coves which running through the northern district of Eheimeanoumawu, the seaward headland, is one of the most important on the western coast of the island. It has a clear entrance about a mile and a quarter wide, with two fathoms at dead low-water of spring-tides. The tide rises 12 feet. The best anchorage is along the northern shore, where the depth varies from five to eight fathoms, in a small, irregular basin, and is entered by two rivers which descend from the high hills at the back of it; they are navigable for boats for some miles from their mouth. In all these harbours there are numerous settlements of natives, and some sea-fisheries.

The river Mokau rises in the Rangitoto Mountains, and runs through a very fertile and moderately hilly district, in which the natives grow potatoes, maize, melons, taro, and tobacco, and the flax-plant covers extensive tracts. The river Mokau is navigable for small vessels, but inside the mouth it is three fathoms deep, and forms a completely sheltered basin. The shores south of the river Mokau, and as far as that of Waiters, are elevated, and consist mostly of marl and a stiff blue clay, or a yellow sand which is 25 feet deep. This country above them is undulating and overgrown with ferns, among which are numerous groves of trees. The soil possesses a considerable degree of fertility, and the vegetation extends to the sea-shore. The country farther inland, to the north, is covered with a dense forest of Eucalyptus, and is overgrown with large trees. It is stated to be fertile, but it has not yet been explored.

Mount Taranaki or Egmont occupies the centre of a projecting headland, and is about 30 miles from the sea, and 3889 feet above the sea-level and above the snow-line. It is a perfect cone, from the base of which the country slopes slowly towards the sea on the north, west, and south; and on the east it is surrounded by higher, and which extends to the tangata Taranaki and the volcano of Tongoaro. The coast forms cliffs of moderate height, which consist of a yellow sandy loam, with a rich mould on the top, which increases in depth towards the foot of the mountain. Near the sea the rocks is to the place is generally 3 or 4 miles from the coast open, and covered with vegetation, especially flax and fern; in the little dales however there are groves of trees or swamps covered with bulrushes and reeds. A great number of streams which descend from Mount Taranaki surrow this region, and form small lagoons at short distances from the place where they reach the sea. The vegetation is very rich round these lagoons. Three miles from the sea the country is covered with a low shrubby forest; but in proceeding farther inland, many large forest trees, especially the rimu-pine, are interspersed, and they increase rapidly in number until a dense forest covers the whole country, which is almost impenetrable owing to the numerous creepers and thorny bushes which constitute the underwood.

Mount Taranaki is the western extremity of a volcanic region, which traverses the island of Eheimeanoumawu from south-west to north-east, and terminates on the north-eastern shores of the Bay of Plenty. The country above Mount Taranaki has been deeply eroded, and it is not known what vestiges of volcanic action are found in this region. But the Rangitoto Mountains contain the active volcano of Tongario and the extinct volcano of Ruapahu. North of the first-named peak is the lake of Taupo, which is formed by the rise of the volcanic formation, from the rents of which numerous hot-springs rise, and which are interspersed with mud volcanoes. Towards the shores of the Bay of Plenty is a large cluster of lakes, some of them filled with hot water, and others sur¬rounded by hot-springs and volatiles, and the whole of the Bay of Plenty itself is the island of Puhia-i-Wakari, or White Island, which has an active volcano.

The Rangitoto Mountains begin on the north with Mount Piringa, above mentioned, and extend south by east to the peak of Tongaro, which is about 1500 feet above sea-level. Their general elevation probably does not exceed 2000 feet above the sea, at least not north of Tongaro. This summit rises to 6200 feet, and that of Rangitoto the snow-drift is 2050 feet, and is supposed to be at least 9000 feet high. Between these mountains and in their neighbourhood the range appears to attain its greatest elevation. But these mountains occupy a comparatively small width, hardly more than four or five miles, according to the accounts of those who have traversed them. On the west of them extends a hilly region, whose general level is probably less than 1000 feet above the sea, but the hills upon it rise about 500 feet higher. On the east of the Rangitoto range is the basin of the Waikato river.

The Waikato river is the largest river in Eheimeanoumawu. Its source is in the Rangitoto Mountains. According to Mr. John Arrowmith's most recent and excellent map, it rises on the northern declivity of Mount Tongario, in a small lake called Rotuwhare, which is 17th feet below sea-level, or higher than the Lake of Thun in Switzerland. But Dieffenbach expressly states that this river, which is called Waikato by the natives, joins the principal stream, which comes from the Ruapahu. If this be the case, the source of the Waikato is near the mouth of the Rangitoto, and the stream to which they would both join it before it falls into Lake Taupo, by three branches, of which the largest is about 100 yards wide. This lake has an irregular shape. Its greatest length from south¬south-west to north-north-east is about 35 miles, and its greatest width 22 miles. The lake is 130 feet above sea-level, and indented. Several rivers fall into the lake from the south, and the common outlet of all of them is the Waikato. The lake is 1337 feet above the sea-level or higher than the Lake of Geneva. The Waikato river leaves the lake at the most north-east point, and flows 500 miles, or about 500 yards wide, and very deep. It runs first north-east, but afterwards in a general north-north-east direction, until it reaches 37° 30' S. lat., when it turns to the north-west, and is joined by its principal tributary the Waipa. In ap¬proximately 120 miles beyond Manukau it turns south, and falls into the sea. The whole course of the Waikato probably exceeds 200 miles. In the middle part of its course, the navigation, if not entirely interrupted, is rendered difficult by numerous rapids and falls, which together form a bay, but is a narrow channel, which at low water only vessels of about 30 tons can enter. But the headlands it is a full river, and when the tide is in it is navigable for large vessels for about 40 or 50 miles. It is used by it is hoped to be improved for a navigation as far as Lake Taupo.

This river rises in the Rangitoto Mountains north-west of Lake Taupo, and runs above 100 miles, of which about 80 miles are navigable for large boats.

The upper basin of the Waikato, or that which surrounds Lake Taupo, and extends south of it to the summit of the Tongario and Ruapahu, has that irregular surface which occurs in all countries which have been convulsed by volcanic agency: High and rugged hills rise to the lake on the north and west, and rise immediately from deep waters, to an elevation varying between 1000 feet.
1000 feet. The hills east of the lake are less rugged, and have a much more gentle ascent. At the southern extremity of the lake is a low alluvial plain, about 10 miles in length, and of a triangular shape. On both sides this flat is bounded by hills, which are broken by narrow ravines. The surface of a great part of this region is bare or scantily covered with mosses, lichens, mosses, and shrubs. The volcanic rocks have been so far decomposed as to form a mould the soil is fertile. The hot springs, fumaroles, solfataras, and mud volcanoes, are numerous. From some of the hot springs the boiling-water rises several feet high, as at the upper Siloam Springs, near the town of Katoa. Some miles north of Lake Taupo the basin of the Waikato assumes a different aspect. The surface of the country is broken into hillocks, irregularly dispersed over the plain, which is perfectly level. All these hillocks consist of tuft or of small pumice-stone cemented together. The level ground consists of the same materials, and as it has undergone only a small degree of decomposition, the soil is poor and maintains only a stunted vegetation of grass and fern. Further north the country improves, and the hillock surface, particularly the paddy of matai (Dacrydium matai) and totara (Podocarpus totara). North of this woody tract the surface consists of hills of moderate elevation, of tuft and small pieces of pumice-stone loosely cemented together by volcanic ash. The vegetation is less vigorous than on the plains, and hollows on the hills and the ravines have some better soil, and are overgrown with shrubs and trees. The lower and more level part however presents a dreary aspect, being clothed with a scanty vegetation of fern and coarse wiry grass, and here and there a stunted flax-tree. The pumice-stone has not undergone sufficient decay to allow the growth of anything else.

South of 38° S. lat. rises a hilly range, which divides the basin of the Waikato river longitudinally into two basins of which the eastern is drained by the Waikato, and the western by the Waipa. This hilly range, which is called Maunga Tautari, terminates near the place where the Waikato turns westward. The lower part of the basin of the Waika she is believed to contain about 60 millions of cubic yards of water, and to be fit for every kind of cultivation, but we have no particular account of it. It will however soon be cultivated, as it has the advantage of being separated from the river Waiko and the Gulf of Shouraki only by a gentle swell of the land, on which a few hills are dispersed. The valley of the Waipa, the largest of the tributaries of the Waikato, is described as one of the most fertile portions of New Zealand. It is about 100 miles long, and from 10 to 12 miles wide. The upper part resembles in many respects the low country on the east coast of the North Island, having a broken and undulating surface, the soil of which consists chiefly of pumice-stone, but the vegetation is more vigorous, and the more level places are covered with fern or coarse grass alternating with groves of the kahikatea, or swamp pine, which are supposed to contain about 60 millions of cubic yards of water, and to be fit for every kind of cultivation, but we have no particular account of it. It will however soon be cultivated, as it has the advantage of being separated from the river Waiko and the Gulf of Shouraki only by a gentle swell of the land, on which a few hills are dispersed. It will however soon be cultivated, as it has the advantage of being separated from the river Waiko and the Gulf of Shouraki only by a gentle swell of the land, on which a few hills are dispersed. The valley of the Waipa, the largest of the tributaries of the Waikato, is described as one of the most fertile portions of New Zealand. It is about 100 miles long, and from 10 to 12 miles wide. The upper part resembles in many respects the low country on the east coast of the North Island, having a broken and undulating surface, the soil of which consists chiefly of pumice-stone, but the vegetation is more vigorous, and the more level places are covered with fern or coarse grass alternating with groves of the kahikatea, or swamp pine, which are supposed to contain about 60 millions of cubic yards of water, and to be fit for every kind of cultivation, but we have no particular account of it. It will however soon be cultivated, as it has the advantage of being separated from the river Waiko and the Gulf of Shouraki only by a gentle swell of the land, on which a few hills are dispersed. The valley of the Waipa, the largest of the tributaries of the Waikato, is described as one of the most fertile portions of New Zealand. It is about 100 miles long, and from 10 to 12 miles wide. The upper part resembles in many respects the low country on the east coast of the North Island, having a broken and undulating surface, the soil of which consists chiefly of pumice-stone, but the vegetation is more vigorous, and the more level places are covered with fern or coarse grass alternating with groves of the kahikatea, or swamp pine, which are supposed to contain about 60 millions of cubic yards of water, and to be fit for every kind of cultivation, but we have no particular account of it. It will however soon be cultivated, as it has the advantage of being separated from the river Waiko and the Gulf of Shouraki only by a gentle swell of the land, on which a few hills are dispersed.

The descent from the table-land to the low tract along the shores of the Bay of Plenty is hilly, and covered with forests, in which the tawai (Leiopusium nervosum), the totara (Podocarpus ferrugineus), and hinau (Euclea) are very rugged on the rocks, with narrow bases. The soil is pumice gravel, richly mixed with vegetable mould. Some of the forests are overgrown with ferns. The forest terminates abruptly, where the flat tract extending along the coast begins; but between the marshy ground and the forest vegetation is not continuous, and there are swampy valleys. The flat tract, from 4 to 6 miles wide, exhibits a vigorous vegetation, indicating the richest soil; the chief plants are flax, fern, and venusia.

On the Bay of Plenty is the harbour of Tauranga, the only opening in the coast for the passage of vessels. There are four fathoms of water over the bar, the channel is about 100 yards in breadth, and, owing to its bending at a small angle, large vessels would have great difficulty in entering it. The great number of pipes that are mostly derived from the volcano of the river Waiko, is to be shipped here. Between Tauranga and Katoa, which lies about 20 miles north of it, the coast is formed by several large islands, which in structure resemble the island of Hawke's Bay, but they are separated from it by narrow channels. Their fertility is equal to that of the low tract along the shore.

In the Bay of Plenty is the island of Tuhua, or Motu Island, which is of considerable extent, and consists of tuffs, bombs, and small pieces of pumice-stone cemented together by volcanic ash. It is inhabited by about two hundred natives, who cultivate the land, and occasionally provide passing whalers with provisions. White Island, or Puhiu-i-Waikari, is small and low; it contains an active volcano, similar in nature to the volcanos of the South Island, of which several cargoes have been brought to Europe.

Till lately it was generally supposed that the eastern portion of the Baikinomauwe, or the large pennisula between the Bay of Plenty and Hawke's Bay, was a high mountain, but it has since been found that no mountains are visible from the table-land of Rotuma, which lies contiguous to it on the north-west, and it is at present the prevailing opinion that this extensive portion of the island probably does not differ materially from the surface, soil, and fertility of the last-mentioned table-land, and that it may eventually become a rich coast. There are however a few summits, which attain a great elevation, as Mount Edgecombe, or Putawata, situated on the north-east coast, and the Maugul, or Mount Ruahine, but they are isolated, and not connected by continuous ranges. The coast-line between Cape Runaway or Te-Kahu, and Table Cape, or Mahia, has numerous indentations, but they are all open, and offer no obstruction to the ships, which can be landed on, except the lower part of the coast of the island. The same is stated to be the case with Hawke's Bay.

No portion of the Baikinomauwe hitherto described can be called mountainous, so far as it is known, though there are a few mountains on the upper drainage of the Kaikori river, and its tributaries in the extreme north and west of the country, on the south-east of which there are a few mountains. But the most southern part of the island is denoted by the name of mountainous: mountain-ranges traverse the whole coast south of a line drawn from Cape Matas-mati in the western coast, to Cape Egmont on the western, with the exception of the eastern coast. They may justly claim the name of ranges.

The eastern half of this region is unknown, with the exception of the coast-line, which, from Cape Matas-mati, situated at the most southern point of Hawke's Bay, runs...
south-west-south to Cape Palliser, or Ka-wa-kawa, a distance exceeding 150 miles, without any indentation which offers a shelter even for small craft. The shore is lined with high rocky cliffs, and behind them the more elevated country is covered with trees. This leads to the supposition that there is a high tract of land which extends from the sea extending over the whole country, and this supposition is supported by the circumstance that not even the outlet of a small stream occurs. It must indeed be an inhospitable country, for it is said that there are not even Eskimo huts present.

Cape Ka-wa-kawa constitutes, with Cape Campbell, the southern entrance of Cook's Strait. West of the cape is a wide bay, which on the west is sheltered by the high lands terminating with Baring Head, or Cape Tura-kia. It is open on the east to the river Manawatu, which affords no safety or good anchorage. It is appropriately called Useless Bay, also Palliser Bay, and by the natives Wai-rara. At the innermost recess of the bay is the mouth of a river, the Wai-rara, which is stated to drain a wide valley which extends far inland between mountain-ranges, but we have no description of it.

West of this bay a headland projects into Cook's Strait in a direction from south-west to north-east. It is traversed by two chains of mountains which terminate in Baring Head on the north, and Cape Palliser on the south. Between these rocky caps a small bay extends northwards, called Port Nichol-son. It is surrounded by high and steep rocky hills, generally covered with wood, except opposite the entrance of the bay, where 40 miles of open land appears in a mile and a half in length. This leads to the alluvial valley of the river Hutt, or Erington, which is surrounded by steep mountains, and extends seven miles inland, where the hills approach each other and form the gorge of the river. The whole region is more, being the valley generally narrow, and enclosed by steep hills, but it widens in some parts to a mile, and in other the hills form platforms on their declivities, which are fit for cultivation; but above the alluvial tract the available land is of the same degree to form areas and is covered by ravines, in which the natives have a few plantations. The bay extends about eight miles from south to north, and that portion of it which is adjacent to the eastern hills is exposed to a heavy swell during southern winds. The street here is very fertile. Above the valley a generally narrow, and enclosed by steep hills, but it widens in some parts to a mile, and in other the hills form platforms on their declivities, which are fit for cultivation; but above the alluvial tract the available land is of the same degree to form areas and is covered by ravines, in which the natives have a few plantations. The bay extends about eight miles from south to north, and that portion of it which is adjacent to the eastern hills is exposed to a heavy swell during southern winds.

The two mountain-ridges which enclose Port Nicholson and the valley of the Erington unite at the source of the river, and are there called the Tara-run range. This chain, consisting of several ridges, runs south and north, and extends to the elevated peak of Rua-pahu, where the Rangi-oto Mountains begin, which are to be considered as their northern continuation. The range of the Tara-run runs broken about the middle by the river Manawatu, and has a portion of it which lies north of the coast by which the river escapes is called the Rua-Wahine range. The geological structure of the Tara-run Mountains is argil-laceous schist, interrupted, especially on the western side, by bulky and irregular dykes of red, black, and greenish Lydian, and the whole is a very coarse and granular, and forms a good stone for building purposes. These mountains apparently do not rise more than 3000 feet above the sea-level. Their external figure is very uniform. They extend in longitudinal ridges with narrow intervals of valleys, which are sometimes flooded. In many places they are overgrown with forest, in others the woody region does not quite reach to the top. They send off from their sides short ramifications, which form masses rather than valleys, from which small rivers flow to the sea or the lower country. As these rivers flow between hills which give them many tributaries, the violent rains often swell them suddenly, and the streamlet becomes a mountain torrent. It then overflows the alluvial land on its banks, and carries with it the stems of large trees, which either remain fixed in its bed, or are buried near the sea-shore, when driven back and left dry by the tide. Quantities of drift-wood are found on the shores of Cook's Strait.

In the country extending from the Tara-run Mountains to Cook's Strait the coast is frequently laid up with Parahou, filled up with the offsets of the mountains. At the last-mentioned place the chain begins to recede from the sea-shore, increasing its distance from the coast-line as it runs north. The mountains are now succeeded by a belt of scrubby sandy hills, crossing it extended through this distance by the widening as the mountains fall back, till, at the Manawatu river, the sandy belt is nine miles broad. Where this belt is traversed by rivers there are large tracts of alluvial soil, cultivated by a comparatively dense native population. It is at this point that the river Manawatu enters into the Port of Mount Ruapahu, and runs along the eastern side of the Rua-Wahine range, southward, in a valley between mountain-ridges, about 70 or 80 miles, when it pierces the range through a cleft by turning westward, and enters the lower country along Cook's Strait. As with all the rivers in Cook's Strait, the force of the current is not strong enough to remove the sand which is thrown up at its mouth by the south-westerly and north-westerly winds, and its depth at the bar is only 3 feet at low water; the tide rises eight feet. The breadth at the mouth is 2000 yards at half-tide. Inside the bar the river deepens sufficiently to admit vessels of about 50 tons, and there is a well defined channel with from one and a half to five fathoms of water, for some miles. The stream is about 300 yards wide. This forest spread over the more elevated land to the base of the mountains. Through all this tract the river is sluggish, and well adapted for steamers. This description applies to the country which extends from the Manawatu to the Wanganui river.

The river Wanganui rises on the western declivity of the volcanic peak of Tongariro, and runs with numerous windings to Cook's Strait. The mouth is more than half a mile wide, and lies on the bar eight feet of water. Vessels of 230 tons have passed over it, but at low-water the sea breaks across the bar. Inside the bar the river grows deeper, and is about 300 yards wide. The banks are here low and sandy, and covered with drift-wood and pumice-stone, which are driven down the river from the surrounding source. At the distance of some miles an extensive flat extends along the banks, which is bare of timber and even of bushes, and in its natural state is covered with flax and fern; it is fine ground for grazing. About 30 miles from the mouth the river flows between hills, which are well wooded, and extend to the base of Mount Tongariro. But in approaching that summit, the country is again more open and flat, though much broken. The natives descend the Wanganui in their canoes from within a short distance of its source.

The coast from the Wanganui to Cape Egmont presents a cliff of moderate height, on the summit of which the land extends in a level plain, which rises gradually to the base of Mount Taranaki. Not far from the sea, and some miles inland, this tract is without trees or bushes, overgrown with fern and flax; it appears to be fit for agricultural purposes or grazing. Further inland the plain is covered with forests, whose vigorous growth shows the fertility of the soil. The drift-wood, which is valuable, is common on Mount Taranaki, or from the hilly tract which runs from that summit towards Mount Tongariro. On these rivers there are numerous native settlements.

Respecting the soil of New Zealand, the alluvial tracts, where they are heavy or hilly, are not so good for crops as the soil, are very fertile, and yield good returns, but the labour of the clearing is very great. The swampy tracts, especially those which are covered with flax, make good land when drained, but the drainage is very expensive. Where the soil is sandy, or the thick flax is found on dry ground, the soil is only of middling quality; but where the fern is short, the soil is good. The wooded slopes of the mountains have generally a good soil, but the thin coating of mud which adheres to their steep sides is only supported by the surface
roofs of the trees, which spread themselves over the ground like a fabric of net-work. When these are removed, the heavy rains wash down the vegetable deposits, and lay bare the sterile substratum of rock or clay. Where the sides of the mountains are formed in terraces, the vegetable earth is not subject to be washed down, and it generally yields a fertile soil. The natives in most cases have established their plantations in the alluvial valleys or in such terraces. In the volcanic regions, the quality of the soil depends on the degree of decomposition which the surface of the volcanic matter has undergone.

The South Island, which separates Eheineomauke from Tavai Poemamoo, is about 150 miles long, and lies from south by east to north by west. At its southern entrance, between Cape Kawakawa in Eheineomauke, and Cape Campbell in Tavai Poemamoo, it is about 50 miles wide; but at its northern and eastern sides, Cape Farewell in Tavai Poemamoo, and Cape Egmont in Eheineomauke, are more than 100 miles distant from each other. At the narrowest part, opposite Cape Te-ra-witi, the strait is not quite 30 miles across. The tide runs from the south at high water, and has a spring of 3 to 4 feet. The prevailing winds near the southern entrance, the greater part of the year, are from the south and south-east, and often increase to heavy gales, augmenting the rush of water through the straits, and making considerable inroads on the eastern and northern sides of the strait. The prevailing winds all the year round blow from the north-west and south-west, and cause a heavy swell to set against the shores of Eheineomauke, between the island of Kapiti and Cape Egmont. This swell has no harbour, and to a great distance from the shore is shallow, vessels are obliged to keep a good offing. The island of Kapiti, called by Cook the Island of Entry, is the most remarkable of the islands of the strait. It is about 25 miles in circumference, and contains a ridge of hills, rising in some places to the height of 600 feet. These hills descend abruptly to the westward and eastward, but at the southern extremity they are low and undulating. At the north-eastern point is an extensive alluvial or lagoon in the sea; it is about two miles wide, and is covered with swampy vegetation. A great increase of the island is cultivated by the natives, and produces potatoes, cabbage, turnips, and Indian corn. It is the centre of an extensive whale fishery. To the east of the southern extremity of Kapiti are three small islands, which, together with Kapiti, form a range which is sheltered from the prevailing north-west winds by Kapiti, and from the south-east winds by the three islands, and affords a safe anchorage for vessels.

Climate—The climate of New Zealand is frequently compared to that of Great Britain, and certainly there is a great similarity between the two countries, so far as respects the frequent changes of the weather, the moderate heat and cold, and the limited annual range of the thermometer, the limited daily range of the thermometer, and the wide range of the thermometer; but the climate of New Zealand is inferior to that of Great Britain because it is colder. The climate of New Zealand and Great Britain is subject to the same changes of the seasons. All these peculiarities are chiefly, if not entirely, to be ascribed to the insular position of both countries; but they are more distinctly marked in New Zealand than in Great Britain, because Great Britain is only at a short distance from the continent of Europe, and its climate must be affected by the changes of weather which take place on this continent, but no country of any extent is near enough to New Zealand to affect its climate.

There is another similarity between the two countries. Those parts of Eheineomauke which are nearest to the equator are only hills, no eminence probably being found north of 38° S. lat. which exceeds 1500 feet, and these parts may be considered to form the most central district of England; but those parts of the island which lie nearer to the pole rise into mountains, which however, with the exception of a few peaks, do not much exceed the elevation of the mountains in the northern part of England. Likewise Eheineomauke is the Llanlith of the islands of Europe, but the mountainous part of Eheineomauke is very narrow, whilst the mountainous part of Eheineomauke is of considerable width. In England, the contrary is the fact. This difference in the conformation of the northern and southern districts of Eheineomauke, combined with the difference of the geographical position, must of course correspondingly affect the climate of these two portions of the island.

We are in possession of meteorological observations made at Auckland in Hauraki Gulf, and at Wellington in Port Nicholson; and though these observations have only been carried on for a twelvemonth, and these facts cannot be considered as conveying exact information; yet the climate of these places, as they seem better adapted to give a notion of the climate of the different portions of the island, than the observation of busy travellers.

Mean of Monthly and Annual Temperature at Auckland, Wellington, and London.

If we consider that the difference of latitude between London and Auckland is only 14° 40', and that of the mean annual temperatures is 9° 50', it appears that the climate of Eheineomauke is rather warmer than could be expected from its mean annual temperature. The difference of latitude between London and Auckland is more influenced by the vicinity of the continent in winter than in summer; for in summer the difference amounts only to 5° 8', while in winter it is 13° 7'. The temperature of the air is more equable at Auckland than at London; as at Auckland the difference between the hottest and coldest months is not more than 18° 9', while at London it is 26° 6'. Dieffenbach says, The place in our northern hemisphere corresponds in its mean annual temperature to Auckland is Montpellier (43° 36'), but in the last place the difference between the hottest and coldest months is 68°. The heat of the warmest month in Auckland corresponds to that of the warmest month in Vienna (48° 12' N. lat.), but its coldest month is somewhat below the coldest month of New York (36° 49' N. lat.). The daily range of the thermometer, which frequently does not amount to more than 4°, rarely probably never exceeds 8°; but on the table-land surrounding Lake Taupo, which may be considered as high above the sea-level, it sometimes amounts to 25°, and in these parts the ponds and swamps are sometimes covered with ice about half an inch thick. On the coast a never experienced: the thermometer never descends below 30°. On the table-land the trees shed their leaves, but along the western coast they are sometimes covered with ice about half an inch thick. On the coast there is never experienced, the thermometer never descends below 30°. On the table-land the trees shed their leaves, but along the western coast they are sometimes covered with ice about half an inch thick.

The climate of New Zealand is very humid. In the months from April, 1841, to February, 1842 there fell 34-49 inches of rain in Wellington. In London the mean annual quantity of rain is 34-10 inches, but in some districts in the West of England double that quantity falls. Dieffenbach thinks that more rain falls at Auckland than at any other place in the world; but along the western coast they are sometimes covered with ice about half an inch thick.
or driven away by the winds. This abundant moisture enders vegetation so vigorous, that it covers even the tops where only a thin layer of vegetable mould is found: it is not injurious to health, as the country is generally so well drained that swamps are comparatively rare and of small extent; besides, it feeds the numerous streams and rivulets, which render the island one of the best-watered countries on the globe. Rain falls in New Zealand in all months of the year, but the largest quantity falls in winter and spring.

Every part of New Zealand seems to be subject to almost continual winds and to heavy gales. The winds blow always, and continues to the middle of April. The weather is agreeably warm; showers fall frequently, but they are short; and the winds, usually blowing from the south, rarely become gales. After the middle of April the weather is more variable, the winds increase in force, and become chillier. This weather continues to the beginning of July, when the bad or tempestuous season begins. Heavy rains occur almost daily, and sometimes they continue for many days together: the wind is almost constant, and often blows with the strength of a hurricane. At Auckland the fair season lasts from October to April and even May. It is regularly interrupted by the heavy rains which occur at the full and change of the moon, and are attended by gales, thunder, and lightning. During the latter part of the year the winds are frequent, and the westernly blows with considerable force. In December and January regular land and sea breezes are experienced. The sea-breeze sets in from the north-east in the forenoon, and from the south-east at night. The thunder-forms are frequent in August, and sometimes heavy.

Earthquakes have been experienced at several places, but the shocks have always been slight, and have caused no damage.

Productions.—Two plants were cultivated by the natives at the time of the arrival of the Europeans, the taro (Colocasia esculenta) and the kumara, or sweet potato (Convolvulus batata). Among the fruit-trees, the most remarkable is the Araucaria, of which the undeveloped flat leaves are made into packing cases and eaten by cattle. The leaves of the Piper excelsum are used as tea. Some shrubs bear berries, which are much liked by the natives, especially the Solanum lavatium and the elderberry-tree (Coriaria aquinata), which are found in abundance, and which produce violent symptoms if eaten by cattle.

The greater portion of the island is still covered with forests. There is a great variety of trees, and perhaps in no part of the globe do they attain a larger size and exhibit more luxuriant vegetation, which is to be attributed to the humidity of the atmosphere. There are eleven species of Coniferæ and Taxaceæ, and they produce the most valuable timber. Among them is only one coniferous tree, the lance-leaved (Phyllocladus trichomanoides), miro (Podocarpus ferrugineus), totara (Podocarpus tootara), mai (Dacrydium maingayi), kawaka (Dacrydium plumulosum), kākākatea (Dacrydium excelsum), rimu (Dacrydium epi- caleum), huta (Dacrydium cupressinum), and another Podocarpus. Other very useful timber-trees are Leiospermum racemoseum, some kinds of Leptospermum and Metrosideros, the Knightia excelsa, Laurus tanarai and Laurus nuts, and Phormium tenax. None of these trees however have hitherto been cultivated for export, but several kinds of native trees have been introduced by the natives to make clothing, and considerable quantities of flax obtained from it are exported; but since the demand for provision vessels which have increased the value of the labour, the natives have gradually ceased to prepare this article for the market. Many swamps are overgrown with a kind of bulrush called raupu (Typha australis), which is a useful buildingmaterial for the natives. The houses of their houses, of which they tie in bundles with a climbing fern: these houses and roofs are impervious to rain.

The most important of the plants introduced by Europeans is the potato, which is extensively used by the natives, partly for food and partly for exportation: every vessel that touches at the island takes large quantities of them. Next in importance is the Indian corn, which is grown everywhere, and in the northern district forms an article of export. Sugar-cane was introduced by the missionaries about 20 years ago, and its cultivation begins to spread. Other grains are not grown, but it is thought that all of those which are cultivated in Europe may be grown, rice excepted. Turnips are very extensively cultivated. They are dried in the oven, wind, or sun, and they keep for a long time. The vegetables are pumpkins, shallots, onions, garlic, beet-root, endive, celery, leeks, purslain, mudishes, Spanish radish, Spanish onions, cabbages, broccoli, artichokes, cucumbers, capsicums, Chilli peppers, and mustard. The pigs have been planted in Eheinoumau, and most of them succeed very well, especially in the northern districts, as some large fruits and the wild pigs are used. Some attempts have been made to introduce the fruits of India, but without success. The bananas and mango-trees do not flourish. Tobacco is cultivated at several places by the natives for their own consumption, and the sugar-cane succeeds very well at Hokitika.

The dog, a smaller variety of the Australian dingo, existed here at the arrival of the Europeans, and is still, though rarely, met with, as almost the whole race of the island has become a mongrel breed. This was the only domestic animal. The natives have succeeded in introducing the horse, cow, ass, sheep, and pig. Pigs are very numerous: they are easily fed and fattened on the fern-root. The other animals are not yet numerous but they succeed pretty well, except sheep, for which the climate is suitable, and cattle, except the exception of a few tame. No wild animals are found in Eheinoumau, with the exception of a kind of bat, called Mystacina tuberculata by Gray. Formerly a native rat, which was eaten by the aborigines, was very common, but it has been nearly exterminated by the Europeans, and is now only found on the table-land of Rotuara. The sea contains four kinds of seals: the bottle-nose seal (Phoca enrona, Linn.); the sea-bear (Phoca hispida); and the sea-bear (Harrazus); and the sea-bear (Pho- lauaus). Their great number, and the scarcity of taking them, first attracted Europeans to the is.
but they have nearly exterminated these animals, and about 20 years ago they were obliged to abandon this branch of industry. There are also eight kinds of whales, the sperm-whale (Physeter macrocephalus); the humpback (Balena gibba); the fin-back (Balena physalus); the pig-backed balaena (Balaenoptera physalus); the berg whale (Balaenoptera musculus); the tuborh, or right whale (Balena antipodum; Gray); and the razor-back. When the seal fishery began to fail, the Europeans directed their industry to the whale-fishery, and with great success. This fishery is carried on partly off Tann's Strait, and partly along the eastern coast of Easheimouawe. The number of whales taken annually by the eight establishments in Cook's Strait is, according to Dieffenbach, 120, and as each whale on an average yields six imperial tons of oil, the aggregate amount is 720 tons, which sells in the London market for 271. The value of the oil therefore is about 20,000 L., to which sum 3000 L. must be added for the whalebone. Dieffenbach however observes, that the fishery has been decreasing for some time, because only the females are caught, and the right whale yields very few. It is consequently a very valuable article of food. Like the shells found in the other parts of the southern ocean, many of these are of a larger size and brighter colours than the species found in the same latitudes in the seas of the north temperate zone of the western hemisphere. In Dieffenbach's work 240 species are enumerated. Very little is known respecting the metals. Gold and silver have not been found; but Dieffenbach states that from the island of Otau, or Great Barrier Island, north of the North Cape, and on the south side of Shouraki Gulf, he obtained specimens of a copper-ore, some of which contained nearly 25 per cent. of copper. Iron-ore is said to exist at several places; coal has been found in the neighbourhood of Hokitanga and at some other places, and also in Teuam's Bay in the island of Tavai Poennamoo. Thick layers of lignite are observed in the cliffs which skirt the western and eastern coasts, but especially in the former. Limestone is found on the west coast on the drier inlets, and some limestone rocks would yield valuable building material. Rocks of this kind are fitted for building materials. Slates are met with in many places. Immense quantities of sulphur could be collected in the volcanic region.

Population and habitation.—The population is composed of European settlers and of the native tribes. The natives call themselves maoi (aborigines), in contradistinction to the foreigners, or paheas. Their number, according to a rough estimate of Dieffenbach, is about 1150. The most intelligent tribesmen of the island stood the defeat of their fellow countrymen with the greatest calmness, and the race was entirely held in the same style, which is one of the great characteristics of New Zealand. The form of the cranium approaches that of the European: in general however it may be said to be of longer dimensions from the forehead to the occiput. The forehead is high, but not very full in the temper regions. The coronal ridge is ample, and there is no coronal suture. The occiput is fully developed. The colour is a light clear brown, varying very much in some persons it is darker, and in others paler, but in all persons it is lighter than that of the islanders of the south of France. The nose is straight and well defined, often aquiline; the mouth generally large, and the lips many persons thicker than those of Europeans. The hair is generally black, and lank or slightly curled. The residuals are white, and some have a thicker and finer texture, and fact are well proportioned. The features are in general prominent, but regular. The other race is distinguished by a less regularly shaped cranial, with a more regular face, much larger, and with a wider forehead, the nose rather more compressed on the sides, by full and round cheeks, and a wider face, and finer hair. The women have coarse hair, which is curly, but not woolly, with but a deeper colour of the skin, and a short and rather proportioned figure. But in all tribes, and in all ages these two races are mixed together, and there is no time or place where one is to be distinguished from the other.

Though there are reasons for considering the natives derived from two different races, this fact is not supported by the language, which is derived from one stock, and does not vary very little from that spoken in the Society and Samoan Islands, which lie on the opposite side of the globe. The languages of the three groups is less than that existing between Dutch and German, as a native of Tahiti on arriving in New Zealand immediately understood what was said in the language of the natives, which is not the case with the Dutch. The difference is greater respect to one another.

It is a well-established fact that this language is derived from the same stock as the Malay language, but of that of the Malays is greatly enriched by foreign words from the Arabic, Sanscrit, and other languages. It is consequently the oldest of the aboriginal until the missionaries and other Europeans produced new ideas and new signs for them.

When the voyages of Cook first made us acquainted with New Zealand, the inhabitants were considered as the most warlike of all the indistinguishable countries of the Pacific. They derived their food from plants which they cultivated, lived in houses constructed so as to prevent them against rain and the weather, were possessed of war-canoes, and wore more clothing than the people of the other islands. But they were divided into many races which were frequently at war with one another. The New Zealanders had not been united in one political body was probably to be ascribed to the numerous islands and steep hills, which afforded to the tribes great opportunity for confederacies or independence. On such hills they built villages, which were fortified with palisades and ditches, and to which small bodies of men could retire when attacked by an enemy. The fortresses were called pa. Their wars were on a large scale, and as they were but a few in number, they began and conducted the battle, and themselves killed and eat their prisoners. Women and children were carried off as slaves. These wars greatly impeded their progress in civilization. But as all the tribes were armed in the same manner, and had not a superiority over another to be able to exterminate them.

The intercourse of the natives with Europeans received a great change. The New Zealanders became acquainted with the use of fire-arms and adopted them as the most efficacious instrument of defence. If firearms had been distributed equally among all the tribes, they would probably have maintained the same relative power in which they stood before that time. But some tribes were more easy of access to Europeans, and they obtained them in the advantage of the others. The tribes which inhabited these districts obtained from the strangers in exchange for provisions, so many guns, that they immediately acquired a superiority over their neighbours, and this circumstance led to the annihilation of several tribes which were inferior to them in numbers. This has taken place within the last forty years, the island has lost the greater part of its population. It is even probable that the whole race would have been exterminated, if the missionaries had not arrived. Other Europeans who were on the island had an interest in inhabitants of this kind, but the missionaries had no such interest, and tried to put a stop to the wars. They have succeeded in the greater part of the island, and even in 1841 some wars were still occurring.
on between those tribes among which the influence of the missionaries had not yet been fully established.

Women are better treated than is usual among tribes which have not made great progress in civilization. The wife is the constant companion of her husband, and they divide the domestic labours between them. The care of the plantations, manufactures the mats, and looks after the children; he constructs the house, and goes out to fish and to war. The affection which the women bear to the men, is extrinsically regulated; they frequently shoot suicide by hanging or drowning themselves, on the deaths of their husbands, by natural means or in battle.

Parents sometimes commit suicide on the death of their children.

A chief person in each tribe is called ariki, and his dignity is hereditary. His authority however is limited to the assembly, which is composed of all the members of the tribe, where his opinion on the affairs of the tribe is of great weight, but he is not invested with any part of the executive. He receives presents from friends and relations, but they are not compulsory or numerous. Each tribe is composed of free men and slaves. The ariki and each free man possess land with well-defined boundaries, and in disposing of the land of a tribe every one can sell or retain his own. It is, in Doubtless Bay, considered the lord of the soil. The slaves are the prisoners of war, male or female, and such of their children as are born in slavery. They have to perform the greater part of the agricultural labour, and are the property of their master, which they never lose, and which is not always considered quite independent of another. They are kept together more by custom and relationship than by any law. When one of them has sufficient authority with a number of indi- viduals, to whom he can refer to his person, build a pa, and found a new tribe.

Their religion is confined to a belief in the influence of spirits on the destiny of men. These spirits are called tua and turua. Atua is properly the deity, though, it is thought, from different parts, and is represented by so many separate spirits; the wairua are the spirits of the deceased, invisible and capable of influencing the fate of persons either in a friendly or in a hostile manner. Their priests are only considered as conjurors and physicians. But at present, as in the majority of the New Zealanders have been converted to Christianity.

The most singular custom among the New Zealanders, as well as among the inhabitants of many other islands dispersed over the Pacific, is what is called tapu, which signifies prohibited. The tapu is attached to different persons, different objects, a canoe is a tapu, and is considered to be caught by the potage of food or drink, but are fed by others until the tapu is taken off, which is done by the priest or priestess by some simple ceremonies and prayers. The breaking of the tapu, if the crime does not become known, is punished by death. On the other hand, if the crime is discovered, it is punished by him whom it concerns, and often becomes the cause of war.

The natives have considerable talent for the mechanical arts, and a great inclination to cultivate the land. Cook observed that when they do not engage in war, they are employed in constructing houses, which were eighty feet long, and constructed with considerable ingenuity. Diefenbach found in several of their pa's, or fortresses, houses with pillars, which were covered over with carved figures: they were executed with great skill and neatness, and have a reference to the military exploits of their pos- sessors.

Though the missionaries have not yet resided thirty years on the island, there are now few persons who had not learned, and even those who live in the country which have only occasionally been visited by the missionaries have acquired these elements of civilization by mutual instruction.

History and Colonization.—There is some reason for supposing that some Spanish navigators discovered New Zealand in the sixteenth century, but nothing is on record which can prove it. We must therefore consider that the islands were discovered by the Dutch navigator Abel Tasman, who reached the west coast of Tavai Poenamoom 149 in December, 1642, near 42° 10' S. lat. He sailed along the coast northward, and at the western entrance of Cook's Strait in the wide open bay called on the coast of New South Wales, but by the Frenchman D'Urville, Tasman's Bay. Here he anchored in a harbour, which he called Massacre Bay, as four of his seamen were killed there by the natives. After taking a few prisoners and making friendly overtures to the eastern coast of Eheinemouani to the most north-west cape, which he called by him Cape Maria van Diemen. From that time New Zealand was considered a part of the Australian continent by the geographers of that time. No European seems to have visited it till the time of Cook, when, in his first voyage, spent nearly six months on the coasts, between 1769 and 1770, during which he circumnavigated the islands and surveyed the coasts. In December, 1769, a French ship commanded by Surville anchored for some time in the Bay of Tauranga, which is now called and is situated near the coast of New Zealand. In 1772, two French vessels, under the command of Marion and Crozet, sailed along the west coast of Eheinemouani and remained for some time in the Bay of Islands, when Marion and 27 Frenchmen were killed by the natives of the New Zealand in his second voyage three times, and in his third voyage for the fifth. Vancouver also visited it in 1791, but merchant-vessels came to it only once during the last century. In fact, these remote seas were hardly visited by trading vessels before the foundation of the British colony at Port Jackson in Australia.

When the colony at Port Jackson had gone through its first trial and began to rise, it began to throw itself over the whole of the open coasts and to proclaim the British law and the British claim with complete success. The first vessels, which entered these waters, were sent by the government of the British crown into the sea in the east New Zealand. As the number of whalers was immense, they were allowed to remain, and they soon learned that provisions and other necessary of life were to be got much cheaper and with less labour in New Zealand than at Sydney, and thus New Zealand began to be the resort of the whalers, who visited the Bay in large numbers without being troubled by any of the geographical position and the excellence of its harbour. To facilitate the intercourse between the natives and the crews of these vessels, a few English settled in that harbour in the year 1816. In the year 1824, and the same period the New Zealand flax began to be considered a useful article, both in England and in New South Wales, and many vessels visited the islands to procure it. The tracts where the Phormium tenax grows in greatest abundance are situated on the west shores of Eheinemouani; and settlements were made there in order to get cargoes for the vessels whose arrival was expected. During the first twenty years of the present century the coasts of Tavai Poonamoom and of Cook's Strait were overrun by sealers and every direction, who caught many thousands seals every season; the skins were sent to China, where they fetched a high price. When the seals began to fail, the whale fishery in Cook's Strait was established. This led to the establishment of several British settlements on the west coast of New Zealand. In that same period a considerable number of Englishmen had settled in Eheinemouani ten years ago. Most of them had married native females, and finding that the country possessed a considerable degree of fertility, that they began to cultivate the landproperty before a regular colony had been established. Meanwhile the Church Missionary Society had directed its attention to the natives of New Zealand, and sent several missionaries in 1814. They were soon followed by some Wesleyan and Roman Catholic missionaries, though their labours were not attended with immediate success, they have so far succeeded, that at present the majority of the natives are Christians, and have learned to read and to write.

The English government, having been informed that every foot of ground in New Zealand was the property of the natives, has directed the attention of the natives to New Zealand, and sent several missionaries in 1814. They were soon followed by some Wesleyan and Roman Catholic missionaries, though their labours were not attended with immediate success, they have so far succeeded, that at present the majority of the natives are Christians, and have learned to read and to write.
somebody; did not think it expedient to send a colony there, and made a declaration to that effect. But the English, who were settled in the island wished to have some protection, and they complained that many runaway convicts from New South Wales had entered the country, where they exercised a pernicious influence over the natives, who were excited by them to many acts of violence against their neighbours and the settlers. This induced the English government to send there a consul or agent to decide disputes between the English according to the law of their country, and to remove vagabonds. This was done in 1833. Previous to this event a French vessel, under the command of M. Hadyn, of the Navy, arrived in the Bay of Islands. It was soon rumoured among the natives, probably at the suggestion of the settlers, that the French had come to seize the island, and that they intended to have satisfaction for the death of Marion and his crew. The natives, alarmed at the news, addressed the British government, and requested it to take the island under its protection. But the government, being well acquainted with the views of the French, did not think this necessary.

In 1836 a French adventurer, Baron de Thierry, announcing himself as sovereign chief of New Zealand and king of Niuhuluwa (one of the Marquesas Islands), published a formal declaration, in which he was styled a king of the British dominions, and to establish an independent sovereignty. He went in 1837 to Hokiana with a few settlers, but being soon abandoned by his companions, he left the country. The declaration of the baron gave great uneasiness to the British government, and they addressed the Baron de Thierry, in a letter of March 14, 1838, praying for the establishment of a regular government in the form of a British colony, observing at the same time, very justly, that the chiefs of the native tribes had too little authority to enact laws for the proper government of the island. At this period the British government had no control over the settlers. The English government was still undecided. But in 1838 an Englishman arrived in London, who had been residing for some time in Easteinomaumee, and had bought an immense tract of land in the province of Easteinomaumee; he wished to dispose of this. This gave rise to the New Zealand Company, which sent there the first regular colony in 1839. The number of emigrants who have gone, up to this time (1843), is between 5000 and 6000. They have settled on both shores of Cook's Strait: the principal settlements are Wellington, in Port Nicholson; Petre on the Wanganui river; and New Plymouth in Taranaki on the shores of the northern declivity of Mount Taranaki. These three settlements are in Easteinomaumee. On the southern shores of the island, in Auckland, settlement has been made on the shores of Tasman's Bay, where the town of Nelson has been built. In 1840 the English government, seeing that it now became necessary to establish an administration for the island, made a regular settlement on the shores of Port Waikato, in the Bay of Shoaraki, where the town of Auckland was built.

The settlements of the New Zealand Company have not given satisfaction, either to the public or to the settlers, and it must be confessed that the persons who have had the direction of its affairs have committed some errors which might have been avoided, and have caused discontent among the settlers and retarded the progress of the colony. Their first and principal settlement, Wellington, has been made in the north on the part of the island set apart for agricultural purposes. With the exception of the comparatively small alluvial tract in the valley of the Eritonga river, the whole country, to the distance of more than eighty miles from Wellington, is occupied by high mountainous lands, which are too poor for settlement. Some ravines contain patches which may be cultivated, but they are too small to support a single family of European agriculturists. The mountains, as well as the level tracts, are covered with thick forests of large trees, and a very close underwood, which renders the clearing of the land so expensive, that a single acre can hardly be brought to a cultivable state for less than from 30l. to 60l. Most of the emigrants possessed capital and hoped to be able to buy a considerable tract of good land, but they find that their intended amount of settled capital is inadequate. In forming the latter settlements, Nelson, New Plymouth or Taranaki, and Petre, the agents have partly avoided this error, having selected districts which contain extensive level tracts. Part of these districts are either not owned or only covered with fern and bushes, so that they are cleared at the expense of from 40l. to 60l. on the acre, these tracts have an inferior soil, which requires great labour to be brought into such a condition as to render the expense. Those parts which are covered with fern have a better soil, but are difficult to clear. The New Zealand Company made another mistake. They did not think that they had bought the land by having put the chiefs of the tribes the sums which had been stipulated. But these chiefs could not sell what did not belong to them. Every freeman of the tribes, who had the land, and most of them were possessed of large tracts, therefore the majority are inclined to sell their lands for a smaller sum. The Company, considering their claims not established, did not from the first adopt the best means to obtain these lands, the natives being informed that their lands had been disposed of by the Company to emigrants who arrived and were impatient to be in possession of what they had bought, continually urged their demands, and placed the agents of the Company under constant suspicion. The chief was still in a disputed state at the beginning of the present year 1841, and especially the new settlements on the Waangamie and in Tasman's Bay. That under such circumstances the settlements cannot be brought to a thriving state is evident. The British government, in concluding the treaty with New Zealand, has entirely put a stop to emigration. Since 1841 very few settlers have gone to the territories acquired by the Company, and many have returned to England. So it happened that some few isolated settlements near New Zealand, especially Port Nelson, a petition to Wellington in the year 1838. In establishing the colony at Auckland, the government at first adopted the principle of the Company being on the rights of the chiefs of the tribes; their sovereignty over all territories possessed by the tribes. But it was afterwards observed that this was not a thing which did not require it. The chiefs have no kind of sovereignty over the coast, and if a sovereignty exists, it is in the tribes, as the most favourable view of the subject, it may be said that the chiefs are possessed of the lands which the individuals who compose the tribe. The British government has lately declared that it assumes the sovereignty of New Zealand, which henceforth is to be considered a part of the British empire, but it does not intend to meddle with the disposition or division of the individual in the possession of his right to dispose of his property as he pleases. The English company having settled among the tribes are under the immediate protection of the English government, which is not tions. The British government has lately declared that it assumes the sovereignty of New Zealand, which henceforth is to be considered a part of the British empire, but it does not intend to meddle with the disposition or division of the individual in the possession of his right to dispose of his property as he pleases. The English company having settled among the tribes are under the immediate protection of the English government, which is not
As already stated, is surrounded by mountains, except at the aluvial tract through which the river Hutt or Eiritonga reaches the sea. These mountains rise abruptly from the water's edge, except in the most south-western part. The valley of the Waikato River, a broad and deep glen, is a strip of about 12 miles long, and two miles wide, the soil of which is composed of sand, shingle, and vegetable earth. On this flat ground, which surrounds that portion of Port Nicholson called Lambton Harbour, the town of Wellington has been built on a base of 1,200 acres in the form of a semicircle round the harbour. The flat ground not being considered sufficient for the town, the hills south of it were included. As these hills are generally too steep to build on, only the more convenient parts were selected for that purpose, and the most important points of the town are nearly four miles from the habour. The harbour is safe, and has good holding-ground. The town and adjacent country contain a population of about 20,000 individuals, but it can hardly be expected to increase much, as the communication with the coasts which have been settled can only be effected over

252
and steep hills or by sea; and the latter mode is as dangerous and laborious as the first is difficult, on account of the continual gales which prevail in Cook's Strait, and the heavy swell of the sea which these gales produce.

Tauri Poonamboo.—This island, which is also called South New Zealand, is separated from Esthecumwane by Cook’s Strait. It extends from 40° 25' to 40° 40', and, if Stuart’s Island is included, to 47° 20' S. lat., and lies between 100° and 174° 30' E. long. It contains, according to a rough estimate, about 50,000 square miles, and is as nearly as large as England, exclusive of Wales. The north-eastern portion of this large island is not known. Seen from the sea, a chain of apparently unbroken mountains is observed at some distance from the shore, and hence it has been supposed that the island is traversed by a mountain-range which rises above the limits of perpetual snow, and that it falls off towards the coast on both sides, so as to leave a little land suited for agricultural purposes. Diefenbach however, on the information of some Europeans and natives, thinks that the mountains form coast-ridges which enclose a sound or the town of Nelson, which appears to be in a more thriving state than the other settlements of the Company.

The central mass of mountains is called Pelorus Ridge, and occupies the whole country between Tasman’s Bay and Cape Campbell. Port Underwood, the site of the Cape Campbell, is three projecting peninsulas, which enclose two very long inlets, Admiralty Bay and Queen Charlotte’s Sound, in which several safe anchorages are found, well protected against all winds, as the surrounding mountains rise to an elevation of 3000 to 3500 feet, and the islands and mountains are either entirely bare or covered with wood. In some places they are overgrown with fern. As the mountains generally rise from the water’s edge with a steep ascent, only a few places of small extent occur near the shore, on the slopes or in the ravines, which are fit for cultivation. On the east side of this mass is an indentation, which constitutes the harbour of Underwood. This port is a deep inlet formed by hills, from which numerous braided streams run towards the sea and form inlets and small coves, in which vessels find good shelter. Port Underwood opens to the south-west into Cook’s Strait, and is frequently resorted to by whaling vessels.

South of Port Underwood the mountains run inland, and at some distance the high ground is continued by the steep slope of Cloudy Bay to the vicinity of Cape Campbell. This elevated cape is the termination of the eastern range of mountains, which is called Kai Koura, and is covered with snow nearly all the year round. The surface of the country between the cape and Cape Campbell is comparatively level, and drained by several small rivers, among which the largest is the Wairau, which has a bar at its entrance. The amount of level land seems to be largest in the eastern end of this river, and the surface of the whole district is covered with the woods and numbers of high trees.

That part of Tauri Poonamboo which borders on Cook’s Strait was, even thirty years ago, the only portion of the island which was inhabited by natives. Several small tribes are settled on the larger inlets and the open sea, where they cultivate the small level tracts near the shore, and smaller patches situated in the ravines. The whole native population of this district does not exceed 150. The whole western coast is uninhabited. For more than twenty years it was visited by many sealers, but the natives generally met with any inhabitants. The circumstances of the coast being so abundant proves clearly that the coast was uninhabited; and as no settlement has been made there, it is probable that in the last twenty years the seals have increased.

We have no account of the west coast, except what we learn from Cook. He says that on this coast, from Cape Farewell to 41° 30' S. lat., there is a narrow ridge of hills that rises directly from the sea and is covered with woods. There are close bounds of pines on them, but this ridge is so abrupt, that it has a ridge of stupendous height, and consisting of rocks is totally barren and naked, except where they are covered with snow, which is to be seen in large patches over many parts of them, and has probably lain there ever since the creation of the world. A much more rugged, barren and desolate than this country extends from a distance of sea cannot possibly be conceived; for as far inland as the eye can reach, nothing appears but the summits of hills which stand so near together, that instead of valleys there are only recesses, and the country has a somewhat better aspect. It rises into hills immediately from the sea; but these hills are well wooded, and the chain of high mountains seems to be at a greater distance from the shores, and their slopes are covered with a great extent of country. For 42° 8' to 43° 20' the mountains lie still farther inland, as the coast-sea consists of woody hills and valleys of very height and extent, and has the appearance of being the southern extremity of the South Island. Many of the valleys form fine canals of water, and the country is so well wooded, that with precipitous rocks. All the indentations of this coast, which are numerous, are open to the western wind on the swell of the sea, except Milford Haven (40° 30' S. lat.) which is said to be very fine; but we have no access of it.

The south-western extremity of Tauri Poonamboo is bounded by elevated chalky cliffs, which are intersected by numerous narrow arms of the sea. These inlets offer safe anchorage to shipping from every wind. The principal of these is called Dusky Bay, Price’s Harbour, and Chalky Bay.

The most southern part of Tauri Poonamboo is the widest part, and in some maps and charts an extensive bar is laid down extending about 20 miles inland; it is said to be due west of the coast of New South Wales, and runs above a hundred miles inland, and is covered with the finest forests. But the accuracy of this account has been doubted on good grounds. It is however certain that no high mountains are observed from it, and that a great part of it is composed more rugged. The country on its banks contains few plantations. Their number does not exceed 1200.

North of Port Otako high land and a bold coast extends to Banks Peninsula. The country has not been visited, but according to the natives there is one large lake inland at some distance from the shore, near which talks abounds, which was formerly used by all the tribes in the manufacture of some of their weapons. This lake is called Tauri Poonamboo, or the Water of the Green Tail, and from it
the whole island has derived its name. No high mountains appear from the sea in these parts.

Bank Peninsula was considered by Cook as an island, but some years since it was discovered that it is joined to the main by a low neck of land. It has an oval form, and is nearly 70 miles in circumference. The surface is very regular, flat and hilly, and some of the hills are visible to sea from a distance of 40 miles. The higher parts are barren, but the lower slopes of the hills are well wooded and the soil is favourable to vegetation. It possesses two harbours. The larger, more spacious, called Akaroa, is near the eastern extremity of the peninsula. It is not farther from the sea than navigable vessels, is easy of access, and well sheltered. On the northern shores of the peninsula is the harbour of Toko-abo, which is not much inferior to that of Akaroa. Pegasus bay, a small estuary, into which two rivers fall, which are navigable, contains some miles from the mouth less round than the harbour rises gently from the sea. There are a few natives.

Opposite the southern extremity of Tavai Poenammoo lies an island. The Rev. J. F. L. Haizlip, in 'The New Zealand Journal,' says the island was discovered in 1810 by Stewart, a captain of a sealing vessel, and called Foveaux Strait. This strait is about 40 miles long and 12 wide on an average. It is very dangerous on account of numerous rocks which are dangerous, and one is very often invisible. The strait is one mile wide. Stewart's Island has nearly the form of an equilateral triangle, and measures in its greatest length and width about 40 miles. The coast is generally rocky and high. Along the western coast it has only anchorage under the lee of some small islands, but on the northern shores there are some small bays which afford good anchorage. The north-eastern shore has one of the finest harbours on the globe, called Pegasus or Southern Port. At its entrance are two islands, which divide into two channels, and each of them is deep enough to admit large vessels. The island is rather mountainous than hilly, and is almost covered with forests, which contain abundance of ship-lumber. Between the hills there are many fine valleys and some large canals, described as being very good and fit for cultivation. The harbours were once the resort of many sealing vessels, and at that period there was a small European settlement, where potatoes and other vegetables were cultivated with success; but since this branch of industry has been abandoned, the settlers have left the island and returned to Sydney. Some small vessels have been built in Port Pegasus.

This is from 'Three Voyages; Nicholas's Voyage to New Zealand,' 'New Zealand,' 'Ellis's Polynesian Researches,' 'Polack's New Zealand; Being a Narrative of Travels and Adventures,' &c. 'Twelve Months in Wellington,' by Hay; 'New Zealand,' by London Geographical Journal, vol. ii.; and John Arrowsmith's Map of the Colony of New Zealand, 1843.'
and are set off by judiciously chosen groups of trees and well-diversified foregrounds. He was however very unsuccessful in disposing of his pictures, and he tried his fortune in etching, but in this branch, though equally clever, he was equally unfortunate. He at last tried his utmost to ply the plate, but when the took it to a publisher for sale, the man offered him merely the value of the copper for it. This so incensed Zegers, that, having told the printseller that the day would come when each print from it would be worth more than he had offered for the plate, he took it into consequence, though he destroyed it. His prophecy came true, for even in Houbraken’s time a print from that plate sold for sixteen ducats. Zegers, broken-hearted at his bad fortune, took to drinking, and, in returning home one night intoxicated, he fell down a flight of stairs and killed himself. The tail Eichinoς, who quotes S. van Hoogstraaten in his account of Zegers, states that he cannot give either the year of his birth or death; in Piglinton’s ‘Dictionary’ however (ed. 1830) the dates 1629 and 1675 respectively are given. Zegers invented a method of printing landscapes in colours upon calico, but his invention was not taken up by any one.

(Houbraken, Groote Schouburg, &c.)

ZEZEGE. [SODAN.]

THE HOLLANDI SHELF. The antient Malacius Sinus (ευκρομάθης ή Μαλακας), is an arm of the sea comprised between the shores of Thessaly and Phocis. It is nine miles long and from three to four broad, points Anderas and Echinos being considered the entrance. Both shores are very agreeable and the head of the gulf is clear, being free from swamps and marshy islands as to be quite inoffensive; the land appears to be fast gaining on the sea. On the northern shore of the gulf are the villages of Ayla Marina, Siliida, the monastery of Ayio Giovanni, and Echinos, which is the first bay on the west, and may have from 500 to 600 inhabitants; the latter, which is little inferior, has considerable Hellenic remains; a large portion of the northern wall is still perfect. A square high Venetian tower stands near the village, and appears to have been from the beginning of the town post. It still remains.”

The southern shore, although without inhabitants, has its recommendation in the magnificent scenery of Mount Eta, and the historical associations connected with the name of Thermopylae, and the river Sperchius, now called the Houbraken, which form the boundary of the new kingdom of Greece.

The whole face of the country hereabouts must have undergone a considerable change since the days of Leonidas. Thermopylae, from which the word derives, no longer exists as a pass, and were it not for the hot springs, it could not be identified with the antient place. (Herod., vii. 198, &c.) Between them and the Sperchius is a mile of flat arable land, and between that river and the southern shores of the gulf there are about two miles, the land of the same open country, though the sea it becomes very marshy. The Sperchius now discharges itself into the gulf by one opening about three miles from its head, and is very shallow at the mouth, which is much obstructed by mud-banks, with only ten to twelve inches of water over them, but within the bar are twelve to fifteen feet of water; the stream within its banks runs about a mile an hour. Due north of the hot springs is the only place where the river is fordable. About three miles higher up (to the westward) there is a good stone bridge, but further on the road is a Turkish guard, and at the southern gulf a confluence.

The springs of Thermopylae, though the rock at the foot of Mount Eta, and are received into a large stone basin which is present the outlet of the basin. When the basin is flowing this basin, they disperse themselves over a considerable distance, running down below, and dissipating and absorbed previous to reaching; the Sperchius, which space is rendered very conspicuous by the aridity and whiteness occurring when the water conveys to be hotter, chalybeate, and to contain a great quantity of sulphur; the odor which they emit is highly offensive. They form small fibrous crystals about the rushbed and a few thick pieces of wood lying in their track, which indicates lime in suspension. The chain of Eta is of limestone rock, and at the southern gulf a confluence.

A little east of the springs is a remarkable hilllock, and near to its base the indications of the deposited soil are plainly discernible, having all the appearance of a sandbank. This is in all probability the spot where the remnant of the Spartan band made their last stand against the Persians under Xerxes. To the westward of the spot a most magnificent ravine with cliffs overhanging on each side to the height of 800 feet, and through it trickles a small stream, which, in winter, appears by the expansion of the watercourse to be a furious torrent, and seems to be the Argo of the Greek story. Crossing this, the road begins to be steep and difficult, till it arrives at a great antient ruins (probably Heraclae) on one of the lower ridges of the mountain, about 1200 feet above the sea, is the first Greek post. The road across the mountains from Xerxes to the Greek sea is not yet followed from it, and the Greeks on Mount Eta, which is obliged to descend into the plain in winter on account of the cold. The path is hewn of such a nature that no horses but those of the cursus, which are accustomed to such roads, could traverse it. They are the only species of the Persian breed of the island, and pass besides feeds bread and bread, with a few vegetables and occasionally sheep may be had.

The deepest water in the gulf is fifteen fathoms: bottom regular, sand. The sea is a great deal calmer here than farther south; in winter a regular gale, but to depend on the strength of land and sea breezes. But Herodotus says (viii. 98) that it takes place daily (viii. 98). (Orob. 10th.)

ZEITZ is the chief town of a circle, in the government of Meissen, and the Prussian province of Saxony. It is situated in a pleasant and fertile country, on the right bank of the White Elster, over which there is a stone bridge of seventeen arches, and which terminates on the further bank, where most of the streets are rather steep. It is surrounded by a wall in which there are six gates, and is divided into upper and the lower town. Having been formerly three of several public offices, it has several public buildings, among them the town hall, the university, the Mint, formerly the residence of the princes of Saxo-Teut. churches, and a Lyceum, which has a good library 12,000 volumes, and many MSS. The public inches, and several public offices. The number of inhabitants 7700, who manufacture calicoes, woolen cloth, leather and starch. There are also many calico-printing and beer claiming, distilleries, and potteries; and the manufacture of white cloth continually flourishing. Many of the inhabitants derive considerable profit from agriculture and the cultivation of their vineyards. Near the town, on the banks of the Elster, there is a park.

The antient bishopric of Zeitz was formed in 990 by Otho I., to promote the conversion of the Wendish Christianity. In 1329 the bishop and his clergy moved to Naumburg as a more agreeable residence, and the bishopric was then called Naumburg-Zeitz. On the death of the late Pflug, the late Roman Catholic bishop, in 1564, the administration of the bishopric was given to the electoral house of Saxony. Previous to this, the electorate of Saxony maintained its supremacy and right of patronage, over the bishopric, in its territorial rights and privileges, for John George, the last elector of Saxony, in his testament bequeathed by his will (in 1562) the bishopric of Naumburg-Zeitz and several other districts to his youngest son, Christian Moritz (Maurice). He was the founder of the Palatine Dyke of Saxony, and was dead in the death of his son in 1718. By an agreement made in 1720, the temporal government was assigned to the elector of Saxony, and the ecclesiastical affairs to the bishop of Saxony privy council. This constitution remained till 1827, when the exception of a tract of 20 square miles, was allotted to Prussia.

The bishopric of Zeitz was in 1827 placed in the new Archdiocese of Magdeburg.

ZELAYA [MEXICAN STATES].

ZELLE, ZELL, or CELLE, is a town in the province of Lippe in the kingdom of Hanover, situated 52° 57' N. lat. and 10° 4' E. long., on the confines of the Pihuse with the navigable Uer, which joins both which...
At the opening of the next decade, the German government acquired the property of the Münchhausen family, which included the estate of Zelle. There, Zelter became involved in the administration of the royal estate, a position that allowed him to exercise his flair for landscape and garden design. He worked closely with the new owner, Christian Friedrich, Duke of Brunswick-Lüneburg, to transform the estate into a garden modelled on the French style. Zelter's designs included a series of gardens, each with its own theme and purpose, and a vast park that combined formal and informal elements. His work at Zelle was widely admired and influenced the development of landscape architecture in Germany.

However, Zelter's involvement in the government also led to conflicts with other officials, particularly with the head of the police, who held a grudge against Zelter for having previously worked for the government in a different capacity. This rivalry and the stress of his government duties took a toll on Zelter's health, and in 1798 he was forced to resign from his position. Following his departure from Zelle, Zelter returned to his previous residence in Weimar, where he devoted himself to his passion for music and gardening. He continued to create gardens for various estates in the region, including the famous garden at the Castle of Colditz. Zelter's contributions to landscape architecture in Germany were significant, and his work continues to influence garden design to this day.

Zelter's career was marked by a strong commitment to public service, both in the realm of music and in the arts. His work at the Royal Court in the 1770s was instrumental in the development of musical life in Weimar and in promoting the cultural and artistic life of the city. His contributions to landscape architecture were also significant, and his work continues to influence garden design in Germany. Zelter's legacy is a testament to his dedication to his craft and to his commitment to creating beautiful spaces for the enjoyment of others.
ZEND-AVESTA, or the “living word,” is the name of the sacred books of the Parsees, which are usually ascribed to Zoroaster. (Zend, a proper name, in Zend-avesta, means "Persian," and was given to the original language to contain the original precepts and laws framed in Zoroaster, and consisted of twenty sections, called Avanes (or “noks,” according to Anquetil), of which we possess the sacred or Zend-Avesta, of which the whole or Zend-Avesta, of which the Zend-Avesta is, and which is by the Parsees called the Vendidad. However, even this work cannot safely be ascribed to Zoroaster; it may contain some fragments of his doctrines, but it cannot possibly belong to a period anterior to the Avesta. (Wilson, [p. 500]) that the sacred writings of Zoroaster were extensively lost during the period which elapsed between the conquests of Persia by Alexander and the elevation to the throne of Artaxerxes, or Ardeshir, the first king of the Sassanian dynasty; for when this prince removed them could only collect fragments of them from the ruins of priests; and it is very probable to this collection we owe the origin of the Zend-Avesta in its present form. It is very diffuse, full of repetitions, and trivial additions, but its merit is great, and it is well worth the reader's attention, as it contains a summary of the Zend-Avesta in its present form.

The original is written in the language called Zend. But Du Perron's translation was made from the Parthian-Avesta, a translation of the Middle-Parthian, and not from the Zend-Avesta, which is the original. Hence, the Zend-Avesta is the oldest of the patrician families of the main libraries of Venice. Its first distinguished member, Nicolo Zeno, lived about the year 1350. The possession of the Zend-Avesta was reserved to the patrician families; and in Italy, family archives to the researches of Cardinal Zeno, Zena was born, the first of the Zend-Avesta, for the most part, when the Zend was spoken.

Nicolò Zeno and Antonio Zeno were sons of Pietro Zenone, a member of the Venetian fleet against the Genoese in the war of Chioggia. Their mother's name was Agnese Dandola. The dates of the births of both brothers are known only from conjecture. Their parents married in 1326.

The name of Nicolo appears frequently in the annals of Venice from 1333 to 1388. In 1335 he took a prominent part in the election of the doge Marco Contarini; in 1336 he was one of the deputies sent to Florence by Venice on the war of the Pisans. In 1337 he was made a captain-general in the war of Perugia, on account of his young age and abilities. A letter of 1379; he is mentioned as having been considered one of the richest patricians in 1381; in 1382 he was one of the six electors who nominated the doge Michele Morosini, and in the course of the same year he was sent as ambassador to Ferrara, towards the close of 1388, he was sent, along with two other nobles, to receive the election of Zeno from the lord of Padua. After this his name disappears from public history; his subsequent career is unknown, having been published by one of his descendants in 1558.

According to this work, Nicolo Zeno, having enlisted on board a vessel of his own to visit England and Flanders was driven out of his course by a storm, and becalmed on the island of Frisland. Here he and his companions were rescued from wreckers by a prince of the name of Zichimi, into whose service Zeno entered in the capacity of pilot, and remained with him one or two years. At the close of that period, having been advanced by Zichimi...
wealth and honours for services in war, he invited his brother Antonio to join him, which he did. Nicolò survived his brother's arrival four years, and died in Frisland. It is impossible to ascertain with certainty either the year in which he quitted Venice, or the mouth of the year from his departure to his being joined by Antonio. The year 1390, the date assigned to his shipwreck by his descendant, is evidently an error, for in November, 1388, he was still in Italy. Most probably he sailed in 1389; two years being the period of the connexion between Antonio and him; and he survived that event four years. This brings us down to 1393 as the year of his death. It is certain that he was dead in 1398, for the family register, making mention of his son Tomaso in that year, describes him as mortuus. 

Of Antonio Zeno's history previous to his setting out to join his brother in Frisland, nothing appears to be known, except that he was married in 1384. According to the conjectures above stated, he must have arrived in Frisland about the year 1391. He remained there fourteen years in the service of Zichmni, having succeeded at his brother's death to his property and employments. At the end of that time (say 1405) he returned to Venice, where it is probable he had been in the same year; for the passage when the family annals which contain the story of the Dracone in 1406, speaks of him as 'quodam Ser. Antonio.'

The controversy alluded to in the outset of this article relates to the countries visited by the Zeni, and whether there was or was not a country called Antiqua in Amundsen's Time. To form an opinion on these questions, it is necessary to keep in view the nature and amount of the information we have respecting those voyages; and with this view we shall set aside all that has been said by commentators, until we have examined the facts themselves. In all the narratives which we know is compressed in twenty-seven pages of a very small and not very closely printed quarto volume, printed at Venice, by Francesco Marcolini, in 1558. The narrative purports to have been compiled about that time by a certain Marcolini. It describes the countries he visited or heard of, and their customs, a Life of his brother Nicolò, and a Life of Zichmni. But this book and a number of letters from Antonio Zeno to his brother Carlo, both written after the death of Nicolò. In one of these letters the writer declares himself to be the author of the narrative; in another he speaks of having seen the island; and in a third, he avers that the island 'was seen by a boy.' — 'These letters (the letters quoted in the book) were written by Messer Antonio to Messer Carlo, his brother; and it grieves me that the book and many other writings on the same subject have perished wretchedly, I scarce know if any exist now.' Antiqua was, however, visited by a quite a boy, I tore and dispersed them as boys will do ('come fanno i fanciulli, le squarcini e mandai tutta 'male'); as I cannot now remember without much sorrow.' Our knowledge of the voyages of the Zeni therefore rests upon a very small and scattered store of materials, from an old and faded map ('marina e vecchia') in the family archives; but he does not assert that it was made by either of the brothers, or even that it was made about their time. From this review it must be apparent how little we know of the Zeni, and how much that little has in all probability been disfigured.

Down to the death of Nicolò the elder, his descendant tells the story in his own person; this part of the book relates to the Viking expeditions, in which the Zeni were quartered under the command of King John. The remainder of the narrative is part of a letter from Antonio to Carlo, in which he rehearsed the story of a fisherman who had been shipwrecked on some far western land, and detained there many years, and added that, as used in Zichmni's 'To visit that country, in which he had accompanied him.' The last two pages are occupied with a fragment of another letter from Antonio to Carlo, in which he mentions the book or books he has composed, and adds that he will work no more, as he hopes soon to communicate with him by word of mouth.

P. C. No. 1775.

The part of the narrative which relates to Nicolò contains the history of three campaigns. In the first, Frisland is subdued by Zichmni, who commands the land forces, while Nicolò Zeno co-operates with the fleet. Zichmni is the lord of the island of Frisland, and at half a day's sail from Frisland, which he had previously captured, he took the king of Norway; and of the duchy ('duchen') of Sorano on the mainland ('fra terra') on the side next Scotland. Frisland was an island rather larger than Ireland. From this island a fleet of the Zeni's vessels, under the command of Zichmni, conducted the fleet of Zichmni to the west, and, after conquering several small islands, turned into a gulf called 'Soderu,' and captured in a port called 'Sanestol,' some ships loaded with salt-fish. Here he was joined by Zichmni, who had learnt over-land that the Zeni had reached the opposite headland of the gulf: the sea, the mark, was full of shallows. He next returns to a part of Frisland named Bondendon, where he learns that Zichmni has conquered the whole island. He sails thence to Frisland, 'the capital of the bot,' is situated in a gulf on the south-east, of which there are many in the island, in which fish are taken in such abundance that many ships are laden with them, and Flanders, Bretagne, England, Scotland, Norway, and Denmark send there for supplies. There are even some points that coincide with it. Sailing westward from the part of Frisland which he was thrown upon, Zeno turns into the gulf of Zoderu (the Zuyder Zee) and the east coast is the Zuyder Zee, which is the gulf to the south-east (the Dollar). The Zuyder Zee is full of shallows (pier di seccagge). The bays of Frisland were at that time frequented by vessels from all the countries enumerated, seeking for cargoes of fish. There are small islands ('isole') in abundance between the Texel and the mouth of the Ems.

The second campaign was undertaken by Zichmni against E本着ld, which is between Frisland and Norway ('sopra la costa tra Frisland e Norvegia'). The expedition does not reach the latter by a direct march upon Frisland, a large but uninhabited island. No mention is made of the relative position of Frisland to any of the other countries mentioned, nor of its distance from them. From Frisland an expedition is made against the islands and Island ('le isole') and Island ('l isorda') with the help of a duchy 'Frisland,' of which he is lord, and which he left to winter there. Zichmni returns to Frisland. Our indications are here still fainter. Proceeding on the supposition that the Frisland of the Zeni may have been the country then called Bres, E本着ld (the land to the east), between Frisland and Norway, may have been the Danish peninsula. 'Islanda' and 'islanda' appear to be merely the singular and plural of the Teutonic word island: the one cannot, and the other does not necessarily apply, to Iceland. Bres approximates to Bresay, the name of one of the Shetland islands.

The third campaign of Nicolò Zeno was a voyage of discovery he undertook from Bresay. He set out in the month of July, and sailed to the north (or north-west) till he reached Engroneland, and from there, he followed the whole description of Engroneland applies to Iceland, and is applicable to no other country. There are, the volcano; the hot springs; the brief summer; the early introduction of Christianity; and the great controversy with Norway. — 'Vengono molti navigi dal capo di sorpa Norvegia e dal Troadan' (Dronteime?). The greater part of the priests we are told are 'delle Isolande'—from the islands; another corroboration of the opinion that the Zeni' Islands,' in this narrative, is not the proper name for any one country. These indications are extremely vague: but there is nothing in them incompatible with the notion that Frisland is Frisland; Engroneland, Iceland; and the intermediate Bresay, the Bresay of the Zeni. Our report of the story of the shipwrecked fisherman, and his account of Zichmni's

Vol. XXVII. 9 E

Digitized by Google
expedition in search of the lands described by the fisher-
man.

The fisherman's story need not be minutely examined
here. Antonio's version of it is sufficiently near the truth
to show that it is really an imperfect account of one of
the many accidental or premeditated visits paid by the North-
man fleet on the coast of the northern region of Ameri-
cas, but it is too succinct and disfigured to add
anything to our knowledge of these expeditions: its only
importance is derived from its having been the motive to
Zichmi's voyage of discovery to the west.

During that voyage Antonio, as was usual, was on a
landfall and has spent many days among the islands and shallows which were the scene of Nicolb
Zeno's first campaign, pushed out into the deep sea' in
the beginning of July. Scarcely was the voyage fairly
begun, when a tempest broke loose and tossed the vessels
about for eight days, swirling some of them, and leaving
the surviving crews entirely ignorant of their whereabouts.
On the return of good weather Zichmi steered to the
west, and reached an island which Zeno calls Lenti, adding, that
the inhabitants said the name.

The account of the voyage of Nicolb Zeno, the first,
who had sailed from Engroneland in the south-east
of Iceland, has, it is true, been subjected to doubt.
It is impossible to say with certainty when or
where it may have been compiled by the Venetians in
the course of preparing the secret of the coast.
It appears that it was made at sea and
published in Venice in 1549, by which time the
voyage of the first king, a son of Dedalus, king of Scotland. Every at-
tempt to make good a landing on the territory of this
Scotch colony having proved unavailing, Zichmi con-
tinued his voyage to the west for six days, at the termina-
tion of which he was compelled to turn back, as
another tempest forced him to seek for shelter before the wind till he was driven to a land
unknown to all on board. Here, as in the western voyage
of Nicolb Zeno, the presence of a volcano appears to
indicate Iceland, but the adventurer had no intercourse with
the inhabitants, and hence nothing is known of the
people of Iceland.

In the course of his voyage Zichmi visited two
places, which he calls the Engroneland, which points to
Iceland. If we assume Iceland to have been its
terminus, there is nothing in the narrative in-
consistent with the supposition that Friesland was the
point of departure, and the bearing of the time occupied,
as far as they are given, rather favours this view.

Confounding ourselves to the narrative of Nicolb Zeno the
youngest, leaving out of view all that has been written by
controversialists on the subject, we have found nothing
inconsistent with the idea that the Friesland of the elder
Nicolb may have been the Friesland generally known by
that name, except that it is called an island. And con-
ceiving that the Zeni appear to have been acquainted only
with the western portion of its shores, we shall regard
in their having taken it for an island. We have
paid no attention to the map published along with
the narrative of the younger Nicolb, for two reasons:—In
the first place, it is impossible to look at it without feeling
confused with Zichmi's map, the projection of which has
not been made much later in the time of the Zeni.
We have discovered nothing in their having taken it for an island. We have
paid no attention to the map published along with
the narrative of the younger Nicolb, for two reasons:—In
the first place, it is impossible to look at it without feeling
confused with Zichmi's map, the projection of which has
not been made much later in the time of the Zeni.

If we assume Friesland to have been the country
between the Zuyder Zee and the Elbe, the Estland between
it and Norway, the lands described by Nicolb
Zeno as the eastern Danish peninsula, 'le islands,' the different island
groups north of Scotland, of which Bressay alone seems
recognizable; and the Engroneland of Nicolb, and the
calculated of Antonio Zenino, Zichmi.
Iceland. In corroboration of this view may be recalled
first, the time and bearings of Antonio Zeno's voyage
from the island to Friesland; second, the Scotch colony
in the first island reached by Zichmi; third, the resort of
venison from Friesland to the northern kingdom of
England for fish; fourth, the commercial intercourse between
Engroneland and Norway—especially it would appear with
Drontheim. The state of Friesland towards the close of
the fourteenth century affords an additional corroboration:
it was a rude country, intermediate between the Huns-
towns and the trading towns of the Netherlands, where the
'stand-recht' (privilege of wreckers) was in full force,
and where pirates founded shelter and purchasers of their
wares. Zeno's account of Zichmi conveys the idea of
the chief of a band of rovers who had wrecked a
small island near Friesland from the king of Norway, and
made piratical excursions in every direction. Zeno's
narrative would lead to the inference that his band were
an indifferent seamen, and previously unacquainted with
the countries they visited.

This view of the Zeni's wanderings is not wholly un-
justifiable: the materials do not admit of certainty.
If it is not tenable, where is Friesland to be found? Sev-
eral writers have felt so strongly the impossibility of
answering this question, that they have been obliged to
make the work of the Zeni west of Greenland. Walckenaer,
seeing the im-
possibility of this, has fixed the most westerly termi-
nation of the Zeni's voyages on the south-east of Iceland to which he
have been led by the striking coincidence of the coast
which they described on the map of Nicolb Zeno the young
the south-east coast of Iceland.

Carlo Zeno, grand-admiral of Venice, brother of Zeno and Antonio, was born about 1334. While yet a

child, the pope presented him to a prebendary of

Patras. At the university of Padua, some debts were

contracted, and Zeno, on the advice of his friends, in

the year 1378, joined the Venetian service, and was

appointed a soldier in different parts of Italy. Hence

home, he found the republic engaged in a war with the

Turks, and repaired to Patras for the double purpose

taking possession of his benefice and serving his

country. In the year 1380, he was appointed captain of

Tenedos to the Venetians. This occurred in 1378, and

the first event in the life of Zeno of which we have

able to ascertain the date so nearly. This acquisition

made Zeno of the Chioggia, in which the Genoese, the

Huns, and the Lord of Padua were leagued against Venice.

The defence of Treviso against the Hungarians was intrusted

to Carlo Zeno. He maintained that frontier post till

the Venetian government, after the loss of the last

of the sea, set sail from Venice, and broke through

eight galleys, and destroyed the

the Genoese fleet without losing a vessel. He took a

march of the enemy's ships in the Sicilian waters, and

summoned the fleet of the Chioggia to meet him

to the Venetians. In the battle of Chioggia, which had

occurred on the 1st of January, 1380., Zeno

head against Spinola in the Archipelago, till the peace of 1811.

The next five years were spent by Zeno in Lombardy in the service of the Visconti. After this he was employed on embassies to France and England, and advanced in succession to the dignified magistracies of Ambassador to the Holy See, and of the Court of St. George. In 1403, while still holding the latter appointment, he was, contrary to the customary policy of Venice, placed in command of a fleet to oppose Bouicault, over whom he obtained a victory on the 7th of October. A few months later he went to Constantinople, and in the spring he left the latter city and proceeded to Persia. In 1406, while still holding the latter appointment, he was, contrary to the customary policy of Venice, placed in command of a fleet to oppose Bouicault, over whom he obtained a victory on the 7th of October. A few months later he went to Constantinople, and in the spring he left the latter city and proceeded to Persia.

Antonio Zeno, the younger, a respectable Greek scholar of the sixteenth century, also belonged to the family of the Zeno. He published at Venice, in 1559, a commentary on the speeches attributed to Pericles in Thucydides, and prefixed an important and beautiful commentary on Concinus Pericia et Lepidi, ex Thesmeide et Sallustio.

Zeno was born at Venice, Dec. 11, 1688: he was descended from a branch of the Zeno family which had been settled ever since the thirteenth century in the island of Candia, from where the Zenoi were obliged to emigrate and return to Venice owing to the Turkish invasion, by which they lost almost all their property. Zeno's mother was a distinguished Greek family of Candia. Zeno lost his father when a child, and was brought up in the most pious and religious manner. He was educated in the service of his brother-in-law, the bishop of Capo d'Istria, who placed young Zeno in the college of the Somaschi at Venice. He displayed early a decided taste for poetry, and after having left college he began to write melodramas, and published about 1400. In 1459 he was promoted to the see of Padua, where he died of apoplexy in 1481. Zeno was esteemed one of the first orators of his age. He left a valuable library and several valuable manuscripts, which were seized by the state of Venice and afterwards sold. His work 'Temistocle' was praised the Emperor Leopold I. of Germany, that he proposed to Zeno the situation of dramatic composer at Vienna with a salary of 4000 florins, which Zeno declined. He received orders for melodramas from the imperial courts of Augsburg and Nuremberg, and was rewarded for them. Since the time of Rinuccini, who may be said to have created the Italian melodrama, that species of dramatic composition had partaken of the vicious taste of the secential, or seventeenth century. Zeno's work was the reformer and renovator of the genuine melodrama as a poetical composition, in which he followed by his successor Metastasio, and afterwards by Sogna, Barbieri, Romani, and others. But at present that the whole of Zeno's composition is fallen very low in Italy, the 'librettii', or words of an opera, being made entirely subservient to the music, so that most of them appear unmeaning when read.

The Zeno family in the midst of its poetical occupations did not neglect grave studies. Zeno had an intimate friendship with Francesco Quirini, who has been repeatedly published. The original Latin appeared for the first time in vol. xix. of Muratori's collection of Italian historians.

In 1717 Zeno was invited to Vienna by the Emperor Charles VI., with the offer of the situation of court poet, to which was afterwards added that of historiographer to his imperial majesty, accompanied with a stipend of 1500 florins. Zeno, however, obtained orders for the composition of a work of more important literary and biographical information. Having noticed many omissions and inaccuracies in the work 'De Historiae Latinis' of G. J. Voss, especially concerning the Italian historians who had written in Latin, Zeno undertook to supply the deficiency by his own/his own/later/his later/his later/later record. He had an intimate friendship with Francesco Quirini, who has been repeatedly published. The original Latin appeared for the first time in vol. xix. of Muratori's collection of Italian historians.

oratories for the imperial church till 1729, when his advanced years and the state of his health made him de sires of returning to Italy to end his days in his native country. Having obtained the consent of the emperor, and proposed young Metastasio to succeed him in his office of court poet, he returned to Venice, where he occupied himself in collecting books and medals, and in preparing his works for the press. The death of the Emperor Charles VI, and the vexation with the Austrian Succession which followed, deprived Zeno of the liberal emolument which he had continued to enjoy even after he left Vienna; but the Empress Maria Theresa soon after granted him an annual pension of 1000 florins, with the continuation of the title of poet and historiographer to the imperial court. In 1747 Zeno sold his cabinet of medals for 20,000 florins to the abbots of the Regular Canons of St. Florian in Upper Austria. His rich library he bequeathed by will to the convent of the Dominicans in Venice, native from whence the greater part has been since transferred to the library of St. Mark. Zeno died in November, 1750, being then eighty-two years of age.

Besides the works already mentioned, Zeno wrote also:
2. "Vi di Paolo Paruta." 3. "Note alla Vita di Cardinal Benzo." These two biographical works, as well as a Life of Sabellico in Latin, also by Zeno, are inserted in the collection of the historians of Venice, for which Zeno wrote also a "Prefazione," or introductory discourse.
9. "Note e giante alla Vita del Guicciardini scritta dal Manzi," prefixed to the edition of Guicciardini's works, Venice, 1738. Zeno's dramas have been published in 10 vols. 8vo., Venice, 1744. A selection of his letters was published in 3 vols. 8vo., 1792; but a more ample selection has been made by Morelli, in 6 vols. 8vo., Venice, 1785. Zeno left many other works published or unpublished.

(Comuni, I Seoli della Letteratura Italiana; Tipaldo, Biografia degli Illustri Italiani; Lombardi, Storia della Letteratura Italiana nel Secolo XVIII.)

Pietro Caterino Zeno, elder brother of Apostolo, was born on the 28th of July, 1666. He took the monastic vows in his 22nd year, and was soon after appointed to teach rhetoric in his order's seminary at Murano. From hence he was promoted to the chair of philosophy at Venice. When Apostolo quitted Venice, in 1718, he confided the task of editing the 'Giornale de Letterati' to his brother, who continued to discharge it till 1728, when he was obliged to resign on account of ill health. He died on the 17th of May, 1729, worn out by the excessive labours with which he performed his devotional exercises. Besides his contributions to the 'Giornale de Letterati,' Pietro Caterino Zeno published a translation of Arnauld's Logic, and translations of some of Bourdaloue's Sermons. He likewise published anonymously remarks on the poetry of Della Cava, and contributed the biographies of Baptisto Nani and Michele Forseari to his brother's 'Lives of Venetian Historians.'

This was followed by another in the same general line, and finally by yet another on the subject of the globes, which in the opinion of Cuvier does not differ from the "Scribante." [Vivendini, pp. 408, 409.]

ZENITH and NADIR, two Arabic terms, imported into Europe with astronomy, to signify the point of the heavens immediately above or below the spectator, and the point below him. The latter term, though still in use in the navigation of the globes, is quite obsolete among astronomers; the former is very frequently employed.

The zenith is the point at which a vertical line cuts the heavens: if the earth were a sphere, this vertical line, so that in which a plum-line hangs, would pass through the centre of the sphere. But the earth being a sphere, the vertical line, which is everywhere perpendicular to the tangent plane, does not pass through the centre of the sphere, but a little nearer to the spectator's side of the equator.

ZENITH SECTOR. This instrument is, as its name implies, a portion of a divided circle, which is employed in measuring the zenith distances of stars. First, it is celebrated operation for determining the figure of the earth, first applied a short arc to a long telescope, the-stating at the same time great accuracy with patient and skillful execution. The instrument which he used for measuring the celestial motions between Malvoinse, Burdian, and Amico, was made and described in his tract entitled 'Mesc a la Fru.' The following is a copy of his plate and description: The instrument is of iron, strengthened with edge-bar, covered with copper in the places required. The limb contains only about the twentieth part of the circumference of a circle of ten feet radius, and divided by transversal lines (Vernier) to thirds of a minute. The bisector is ten feet long, and the wires are illuminated from the top or by an aperture on one side of the telescope. The plum-line is enclosed in a tin tube, to protect it from the wind, and the observations were always made in a close apartment through an aperture in the roof.

The figure shows all the instruments, and also the sectors for setting the axis vertical, which it is when turning the instrument round, the plum-line being in the same direction of the limb. In making the observation, suppose the axis to be vertical and the limb to be towards the reader, as in Fig. 1 (the limb should also be the plane of the meridian, and the telescope directed towards it). Now if the eye be fixed through the centre, parallel to the line of sight of the telescope, the angle between the line so drawn and the plum-line is the zenith distance of the star; for at this point where the arc cuts the line supposing it at the pole, the line supposed not to
yet defined, except by its parallelism to an optical and instantaneous, and as a consequence, no. Hee off however the division on which the plumb-line beats. Turn the instrument half round on its vertical axis, when the plumb-line remains on its former division, and the telescope points to the same zenith distance, but on the other side of the zenith. It is evident that the telescope will no longer be in the same position, because the sector must be turned on its horizontal axis through twice the zenith distance; and as the plumb-line always keeps parallel to its position, and passes through the centre, the division on which it now beats must be distant from the instrument a divided height, which, passed through, that is, by twice the star’s zenith distance, and the division which bisects the two readings is the zero point, or reading which corresponds to the zenith. It is not necessary that the star should be observed in both positions, the sector will do, and the construction of the sector continue to have the same position with regard to the line of sight. In this case, return on a following night will serve just as well for determining the division which corresponds to the zenith direct to the telescope.

If this reading is not that which was intended by the maker, the difference is called the error of collimation, and is applied as a correction, additive or subtractive, to all the observations, according as they are on one or the other side of the true arc.

Picard enters into no details with respect to his observations, but gives at each place a zenith distance, which is the mean of a considerable number. He only observed one star, and that to the north, viz. the Knee of Cassiopeia [30°], and in his followings, he remarks that this star would have been more difficult to observe, and that if the star had been between the two zeniths, the error of the instrument (the division corresponding to the zenith, or error of collimation), which might have been imperfectly done, which was a degree in Hooke, would have been, if the star had been between the two zeniths, because then the sum of the two observations must have been taken; whereas when a star is always observed on the same side the zenith, there is only the difference to be taken, which must be corrected, and that is the same as in the imperfect meridian.

In 1674 Hooke published 'An Attempt to prove the Motion of the Earth from Observations,' in which he describes the instrument he contrived for observing the distance of 9 Draconis from the zenith of Gresham College, and in which he also demonstrates the variations which might occur. This consisted of an object-glass of 35 feet focus length, fixed at the top of the house, and referred by two plumb-lines hanging from a bar in the object-cellar and pinned to the roof through the floors, to a system of wires below. Before each observation, Hooke set certain marks in his wire-cellar to the plumb-lines, then fixed the wire-cellar, removed the plumb-lines, and bisected the star: after the observation, he verified the position of the wire-cellar, and came to rest, lines which he admired in this simple and ingenious contrivance, but his manuscript for noting the small variations seemed clumsy and inelegant. "Inconvenient weather and great indisposition in his health" limited Hooke's observations to four in number, from which he erroneously concluded that there was an annual parallax of the earth's orbit, and therefore that Copernicus's theory was true. With very little alteration, such as a user correct for the plumb-lines to the eye, a dot was then fixed above in a counterpoise, and a screw micrometer for a moment. Hooke's instrument, or his idea of using a deep dry well for the telescope-tube which were adopted, we conceive that most accurate determinations might now be made.

Picard, however, first discovered a motion in the stars which they could not account for. Picard, Roemer, and Flamstead all found that the position of Polaris varied at different times of the year, and Flamstead fancied that the change was due to parallax. In or about the year 1675, Mr. Nathaniel Hooke, a gentleman at Kew, employed Graham to make him a parallactic telescope, so called from its object, viz. to discover the change of place in the stars occasioned by the earth's change of position in her orbit. This is described in Smith's 'Optics, I., p. 7,' and fulfills Mr. Molyneux's own words in Bradley's 'Miscellaneous Works and Observation,' p. 93. It consisted of a telescope 25 feet long, with a short cross axis at the upper end, just at the place of the object-glass. This axis was so adjusted on its support that the telescope would remain in the same position when hung on one end of the axis and passed over a dot in a plane fixed on the tube near the eye-end. The telescope was drawn forwards in the meridian by a string and weight passing over a fixed pulley, and pulleys back by an anta- chine with a divided mark, and in that manner the image in the object-glass was made to pass under the eyepiece, and the object-glass was moved by the screw, which made the observation, the plumb-line is first made to bisect the dot by the screw, and the division read off; then the star is bisected also by moving the screw, when the division is again read off. The revolutions and parts through which the screw was put together to make the observation, the plumb-line is first made to bisect the dot by the screw, and the division read off, if there is no change in the relation of the object-glass and wires to the axis and dot.

Observations were made at Kew for some time with this instrument by Molyneux, Lord Bolingbroke, and Bradley; and in 1727 Bradley had a zenith-sector constructed for Graham by which he made his celebrated discoveries of aberration and nutation. There is a short description of this instrument by Molyneux, in a letter of his to Bradley, in the 'Miscellaneous Works,' &c.; but Bradley himself gave no description in his Memoir on Aberration (Phil. Trans., vol. xxxv., 1677.), and in one of his letters, to which is a word of Bradley, in the 'Miscellaneous Works,' vol. iv., p. 1 satisfied himself by referring to the description of a sector on a similar construction. (Dégrés du Méridien entre Paris et Amiens, 1740.) This last-mentioned sector was made by Graham for the measurement of the meridian arc. A great part of the work was on this sector, and by the permission of the Lords of the Admiralty, this account is by the astronomer-royal, who directed the alterations required to fit the sector for the field. The principal parts of this instrument, as originally made by Graham, was a telescope with a short sector attached to the eye-end, and a short cross or transit-axis to the object end, which causes it to move in the meridian when properly adjusted. A plumb-line passes over a fine dot at the extremity of the upper axis, and beats on the divided sector below, that is, both the dot and sector are below, but still hangs perfectly free. To prevent any disturbance from the wind, the plumb-line is screened by a tube, and the bob hangs in water that it may weigh the plumb-line and move the telescope. The meridian correctly, as well as to get a proper fixing for the clamp and mierometer-screw, another arc is fixed to the wall, and the telescope carries a frame with rollers at its eye-end, and is thus kept in contact with the fixed arc before and behind. A clamping apparatus, which slides along the fixed arc, and can be attached to it by screws in any position, carries a fine screw with a micrometer head, which pushes the telescope by acting on a piece of hardened steel, while the telescope resists either by gravity or spring. There are numerous pins and contrivances for different adjustments, which will be easily understood from Mr. Airy's account. In making the observation, the telescope is first to be set, or nearly so, to the star, the bisection of the upper dot is verified, and then the observer, if below, is bisected. He is then moved by the screw forward, for instance, and the micrometer head is to be read off. When the star is in the centre of the field, it is bisected by carrying the screw still forward, and the micrometer is again read off. Finally, the sector is then bisected forward, and the star is bisected, and the micrometer read off. A simple proportion will give the quantity, which is to be added to the first reading, or subtracted from the second reading, in order to get the reading corresponding to the star.* Bradley’s sector is originally

* In some of the books referred to, it will be seen that the dot bisected by the sector is the same as that bisected by the sector. This is not the case, for in the reading taken, but a screw which carries weight never reads the same when moved forwards and back wards, and it is always necessary to carry the screw the same way in the same operation.
made was not reversible, and therefore only fit for measuring differences or variations. When, after its removal to Greenwich, actual zenith distances were required, the instrument was shifted across the room, from the east to the west side, where a second fixed arc, &c. were ready to receive it. We need not say that this was very objectionable, as such an operation would be made at any rate, in bisecting what might be the relation of the parts of the instrument, and so to lead to untrue conclusions. Even while it was at Wanstead, and considered to be impossible, a slight change seems to have taken place, which has been investigated by the "Reduction of the Observations taken by Bradley at Kew and Wanstead," Oxford, 1832. In remounting it, the astronomer-royal has given the property of reversion very satisfactory, and M. Maclare's observations with it are of extraordinary accuracy.

A sector was used in the measurement of the meridian in France, by Cassini de Thury and La Caille, which greatly resembled the sector of Piacart, except that the arc was of much greater extent, being 22° and framed with three radii. The telescope was fixed at the back of the instrument, so as to be at once more firmly fastened and out of the way of the plumb-line; and, lastly, its micrometer-screw was applied to the wires of the telescope (sometimes called the interior micrometer), instead of moving the whole instrument. By this mode of observing, the instrument is set approximately to the star, and the nearest dot accurately bisected. When the star is in the centre of the field, it is bisected by the micrometer-screw which carries a wire in the focus of the object-glass, and thus the excess or deficiency of the nearest dot is determined. This instrument in the application of the micrometer-screw is due to the Chevalier Louiville, and in this respect we prefer the French to the English construction. See "La Méridienne de l'Observatoire Royal de Paris vérifiée," par M. Cassini de Thury, Paris, 1740. The sector is figured on page 31, and described on page xlvii.

Boëguer and La Condamine, in their measure of the arc of Peru, were compelled to fabricate their own zenith sectors, and adopted a very elegant mode of graduation, the measure being given by La Condamine to their colleague Godin. The telescope and arc being prepared, a star is selected which has pretty nearly the same zenith distance at both extremities of the arc of the meridian. Now calculate approximately the value of the chord of the double zenith distance of the star, and find what fractional part it is of the radius. Suppose it is nearly \( \frac{1}{2} \) of the radius, then take a beam compass, mark two dots on the arc, and step seventeen times with the same opening along the radius, and so fix the dot over which the plumb-line is to pass. The instrument is no longer moved, and the operation follows:—After being adjusted to the meridian, the plumb-line is made to pass over the upper dot and one of the lower dots, after which the star is bisected by the interior or Louisville micrometer. On a following day the instrument is removed, the plumb-line and the upper dot, and the lower dot, the star is again bisected by the micrometer. It is plain that the double zenith distance of the star, corrected for refraction, aberration, etc., is measured by the arc subtended by the star, dot by the two dots below &c. the sum or difference of the micrometer readings. But the arc is, by construction, that the sine of which is \( \frac{1}{2} \), which is found from the tables; and the value of the micrometer readings being also known, the zenith distance of the star is found. The operation may be repeated at the other end of the arc with the same star, and using a different submultiple of the radius. See "Mesure des trois premiers degrés du méridien," par M. de La Condamine, Paris, 1751, pp. 185 et seq.; "Figure de la Terre," from the Memoirs of the French Academy, 1751.

We insert here the method employed by Maupertuis, La Caille, and others to ascertain the value of the total arc of the sector. A line of considerable length was carefully measured from a well-defined spot and a signal erected; the same signal was used in the same place, and the line had a length as very nearly subtended at the spot the arc to be verified, and here a second signal was placed. The sector was then laid horizontally on a bed prepared for it, the centre being exactly over the defined spot, and the telescope is set to the first arc set out. This is done satisfactorily, a fine line was stretched over the centre and the first dot of the divided arc. Now shifting the sector round, the second signal was bisected, and it was seen what division was bisected by the line which continued to pass over the centre. The true angle is evidently marked on the ground, and is calculated from the fixed length of the perpendicular and the distance. The value of the arc read on the sector is compared with this, and the error of the total arc detected, which is at once corrected, and the value of the arc so determined. At present the value of the total arc of a sector would be determined by a comparison with the mural circle.

In 1775 Bird erected a zenith sector at the Observatory of Oxford, which in all respects respects similar to Cassini, but it is fixed to an upright pillar which revolves so that the instrument is reversible. From some cause or other, though observations have been made with this instrument, they have not been considered satisfactory. It appears, however, that after a considerable time, an instrument of considerable accuracy, and capable of doing good work, though perhaps inferior to the French sectors, viz., ascertaining the index error of the mean declination instrument, has been supplied to modern use by observations by reflexion.

The zenith sector of Ramsden, which was used in the trigonometrical survey of Great Britain, and in the British arc, is described and figured in detail in the "Phil. Trans." for 1803, and in the second volume of the "Account of the Ormance Trigonometrical Survey of Great Britain." The instrument has consumed a considerable part of the Tower in 1781. This instrument is very fully detailed in the section referred to, it is useless to enter into particulars here. Ramsden viewed the upper dot by a long memory, which was placed in the eye, and the distance of the nearest dot determined. This instrument has the chance of deranging the bisecting by mounting to the north. The Astronomical Observations with Ramsden's Zenith Sector," reduced by Lieutenant Yolland, R.E., have recently been published (1842) by order of the First Ordinary, 1740.

After the destruction of Ramsden's sector, Colonel Go, applied to the Astronomer Royal, for his advice as to the best form of instrument for determining latitude and the field. The construction given by Mr. Airy and Ramsden, and approved by the Astronomer Royal, has been adopted; and the great merit of the instrument has been such that it has been adopted by all astronomers, and is in use in almost every observatory in the world. The division of the arc is marked off in one piece and strongly framed, carries back three levels, one tube against which the beam is bent off at the moment the star is bisected, determines the position of the axis with respect to the zenith. The telescope-frame with the eye and object end is cast into a solidly braced piece, and is fixed at its middle, while the two sides move freely for a few degrees on each side the plane. The divided arcs are graduated on the vertical arc in its top and bottom, and there are four micrometer microscopes, one at each side of the object, the tubes being bored in the solid telescope-frame. There is a wire-micrometer in the focus of the telescope. A stop to the axis enables the observer to use the instrument exactly half round by touch, and also instaneously. The observations are made in the following manner:—the instrument being pretty near in the meritian and axis vertical, the telescope is set nearly for the star, and the microscopes are read off. Before the star reaches the centre of the field, the observer bisects it with the upper dot, reads both ends of each level, and the whole instrument is turned half round and the star is again observed, the bisecting being now performed by the tangent-screw of the telescope-frame, the time is again noted, and the sector takes off the arc above and below are read off by the micrometer microscopes. In this way the double zenith distance of a star, free from all error of collimation or of the vertical axis, can be obtained in a few minutes. This instrument has been in use from the time it was invented and found very satisfactory.

The telescope is one of 34 feet focal length, and the instrument bears the same relation to a mural circle that the ordinary sector does to a quadrant.

When Troughton first proposed the mural circle as the best form of instrument, great doubt was thrown on the practicability of observing by reflexion with sufficient nicety, and in that case a mural circle does not reverse, a supplementary instrument was added. In Europe the instrument was first employed at the French Academy, for laid plan position, and the object was exactly half round, and the whole instrument was turned through a complete circle. The observer then bisected the star with the upper dot, and the mural circle was read off. The virtual axis of a star is given by the position of the triangle completely described; and the formula of the instrument is given by the position of the star in the triangle. The formula of the instrument may be given by the position of the star in the triangle. The formula of the instrument may be shown in the following manner:—the instrument being near the meridian and the axis vertical, the instrument is laid on the bed and the circle is read. The star is then bisected with a beam compass, and the circle is again read. The difference of the circle read will give the zenith distance of the star, which is the formula of the instrument. This formula is given by the position of the star in the triangle, and the position of the circle on the instrument. The formula of the instrument is given by the position of the star in the triangle.
was wanted to show the position of the zenith or horizon. 

Partly on this account, but chiefly to set the constance of aberration and precession with the greatest precision, Broughton planned what he called a tube, consisting of a telescope of 25 feet focal length, without any sector, and in which the variations of zenith distance of γ Draconis and those zenithal stars were to be measured by a micrometer-screw.

The instrument has not been described, indeed it is not yet constructed; or, if the description is published, several improvements have been made in its construction by Mr. Airy since its appointment as astronomer royal. The telescope rests on its lower end, continued beyond the axis, on a piece which has adjustments for verticality, and the object of the instrument is to allow the telescope to be rotated about a Y-bearing. The wires at the focus are moved by a micrometer-screw, and the star and wires are seen through diagonal four-glass eye-piece. The plumb-line hangs within the tube, and is viewed above and below by micrometer microscopes. Instead of adjusting the plumb-line before each observation, it is bisected by the micrometers after the observation, and a correction applied which is reduced from the upper and lower readings. Mr. Airy, labouring with this sector to show that it will work, in reversing the instrument, has given a double suspension of the plumb-line and made the instrument reversible on a star in the same night, by using a stop as in the ordnance sector. The observations with the zenith tube are printed in the Astronomer Royal's annual report. This is the observation made in the test of the instrument.

The zenith sector has not been much used upon the continent since the great surveys made in the middle of last century for ascertaining the figure of the earth. In the French arc from Dunkirk to Formentera, the latitudes were taken in the direction from the south of the shore. There are reasons to suspect that error has been committed. More recently, the transit in the prime vertical as employed in Germany and Russia for ascertaining differences of latitude, and as it would seem with great equal advantage and nearly in the meridian, the observations have been constructed by the imperial observatory of Petropavlovsk, of which a most favourable account has been given by Professor Struve. While admitting the excellence of this kind of instrument for telescopes of moderate size and not seeing one can easily, far less suspects the zenith sector when made reversible and of the proper magnitude.

Some years ago Mr. Babbage proposed a construction for making a double suspension of the plumb-line. This may perhaps be applied in the following manner:—Conceive a parallel ruler to be placed upright, one of the bars being made into a vertical axis with the necessary adjustments, and the other carrying a telescope. In such a position it is clear that the telescope would continue parallel to itself whether the ruler be open or shut. But if one of the bands is a little longer than the other, then a very large angular motion of the bar will give a small angular motion to the telescope, which can be easily made with tolerable accuracy, the latter angle can be computed with great exactness.

Exquisite workmanship would no doubt be required to make such an instrument answer, but we think that for this and other differential purposes Mr. Babbage's suggestion deserves more attention than it has yet met with, especially where telescopes of limited size are used.

The adjustments of a zenith sector or zenith tube will differ according to the construction of the instrument. Whichever be decided upon near the zenith must be got from observations with another instrument, and the star made to pass the meridian-wire at the calculated time by the proper adjustment screws.

When this is done and the telescope secured, a star must be made to pass along the declination-wire (this should be carried by a micrometer-screw) by twisting the wire-cell, when the adjustment for a fixed zenith telescope is complete. If the telescope rest on a cross axis and carries a sector, the cross axis must be made horizontal, the transits of stars towards the extremities of the arc must be observed, and the azimuthal deviation ascertained [Transitj and corrected by which an error is known, and an error being known, the cross axis at top and fixed arc below must be turned so as to make star pass at the right time.

When the instrument is reversible, the axis is first to be set truly upright. Suppose the instrument in its meridian position nearly, and face east, read off the division bisected by the plumb-line, or the two ends of each level. Now turn half round, read off again, and bring, by the adjusting screws, the plumb-line or the levels halfway to the first readings, and finally adjust each level by its own screw to read each end alike. If this be carefully done, when the instrument is restored to its first position, the plumb-line or levels will remain undisturbed by the last reversal. Now turn the axis of collimation, and correct whatever changes is thereby caused, by the east and west screws of the axis. The axis is now vertical, or by a repetition of the process may be made so. The next adjustment is to make the line of sight describe a great circle in the plane of the instrument. This may be done as described above, from knowing the true time; or by observing one star or two stars near the zenith in reversed positions, when the disagreement between the observed and computed difference will give the quantity to be applied to an end. In a modern instrument this adjustment would be by antagonist screws carrying the wire-plate. If the instrument be a simple zenith tube, make a star run along the declination-wire, and the adjustment is finished. With a sector place the two meridian-wires at the same distance from the zenith star, which gives the time. Then by turning round the axis, make an extreme star pass at the proper time and clamp the axis. In the new ordnance sector the instrument rests on a tray which is adjusted as to level by thin plates; an end of the tray is fastened to the sides of the tray. Finally, twist the wire-cell till a star runs along the declination-wire. A comparison of the zenith distances of the same stars observed in reversed positions on the instrument, will give the error of collimation, and this may be corrected if the observer wishes, but it is better to leave it untouched, and to consider the sum of two observations, Face East and Face West, as a double zenith distance.

According to the value expression (\(\frac{\ell}{\ell^2}\)) used by Digonc M. Laxit, he was enjoying his greatest celebrity about b.c. 404. He visited Athens in company with Parnesides, and they were present at the Great Panathenæa.

Parnesides is described by Plato as at this time a man advanced in years, with his hair quite white, but of a handsome and pleasing person: he was then about 60 years of age. Zeno, who was then near 40, is spoken of as a tall and comely person. If we place this visit to Athens, in b.c. 404, we have the date that Zeno was born about b.c. 404. The authority for the visit to Athens is the 'Parnesides' of Plato, which so far as relates to this historical fact, is generally admitted to be sufficient authority.

It is of opinion that Zeno, as well as Parnesides, was employed in legislating for Elea. He probably lived till the commencement of the Peloponnesian War, or at least to b.c. 430. According to Plutarch (Periher) he was the dead are reported with much diversity. He is said to have conspired against a tyrant of Elea, who was variously named, and, on the discovery of the conspiracy, to have been put to death in a cruel manner.

Many works were attributed to Zeno, which says Diogenes, were full of wisdom. One of his great works he is said to have read at Athens, on which occasion Socrates
was present. Though the 'Parmenides' of Plato, which is the authority for this reading at Athens, cannot be taken to be literally true in all respects—for Sostratus, then a young man, is represented as discussing with Zeno—yet there seems no reason to doubt the fact of Zeno having read his work at Athens. The object of this work, which was divided into several parts, was to show that it is impossible to conceive things as being Many, and this conclusion was derived as a necessary consequence from the supposition of things being Many; for Zeno showed that if we suppose things to be Many, then the same things are both like and unlike. Now, it is impossible to conceive the same things to be both like and unlike, and therefore it is impossible to conceive things to be Many (ὅπερον εἶ ἐσθαναί ἐν τῷ ἀνάμνησι ἐσθαίναι καὶ τῷ ἀναμνησθεῖν, ἀνάμνησις ἢ καὶ πολλά ἐστιν). Plato, Parmenides.

Zeno said he had been the first who used the form of the dialogue in the Parmenides. Parmenides, therefore, must have added the doctrines of Parmenides, for he is said to have added little of his own to what his master did. His method was, to assume the truth of received opinions, and then to show the contradictions to which they led; and, accordingly, Aristotle (as quoted by Diogenes Laertius) calls him the inventor of Dialectic; not of Logic, as some modern writers have it.

Zeno's work in defense of the Doctrine of the One was, as he himself describes, designed to support the opinion of Parmenides against those who ridiculed it on the ground that if there is only One, many absurd and inconsistent consequences must flow from the doctrine; and, accordingly, his work is in opposition to those who say that the Many is Possible, and his aim was for its special purpose, to show, that many more absurd consequences will flow from their hypothesis of things being Many, than from the hypothesis of the One, if a man rightly follows them up.

This is the key to the explanation of what we know of the arguments of Zeno.

Zeno asked Protagoras if a single grain of millet, or the ten-thousandth part of a grain, would make a noise in falling. Protagoras said it would not. He then asked if a medimnus of such grains would make a noise in falling; and the answer was, Yes. Zeno further asked if every moment in space Köπος, and therefore is at rest, for nothing goes on in the space in which it is; but that which does move is at rest, for everything either moves or is at rest. Aristotle replies, that this argument is false: it supposes that time is composed of indivisible moments and he adds, that time is not composed of indivisible moments nor is anything else composed of such parts. It is not possible to pass from a single space unit to another in a single moment of time. The argument is supposed, by those who say motion, to pass from one point in space to another in every position between these two points it is said, where it is; and when a thing is where it is, it must be where it is, according to Bayle, who seems not to approve of Aristotle's solution offers one which is no better. Zeno's difficulty remains. There is no absolute motion: we only conceive motion relatively.

There is a fourth argument, which is well stated by Bayle.

If we view the arguments of Zeno as mere sophisms, we view them wrongly. They touch the fundamental conceptions of all science, and Aristotle means that they cannot be ignored. His arguments are directed to show the difficulties inherent in all our conceptions of motion. When, as Aristotle says, he denied the notion and said that the space of a stadium being passed over by a tortoise, the appearance of a stadium being passed over by a tortoise, that we could conceive how it was possible, he denied that we could conceive how it was possible. There is no authority for saying that he denied the existence of the One, even if he denied the existence of indivisibles. He did not admit that the things of the One could be known, for he said they were too small to be able to hold them, what things are (τὰ μικρὰ). His speculations pass us by the difficulty of determining the notion of indivisibles, and to the consequent conclusion of all things
One, without parts, an absolute, immovable, inconceivable Existence. Nothing particular is said of his theological doctrines, and the few physical doctrines that are attributed to him are not worth mentioning.

(Diodgenes Laertius, *Zeno of Elea*; *Ritter, Geschichte der Philosophie*, vol. 1; and the *Fragmenta* of Zeno, by Ritter and Peller, in their *Historia Philosoph. Græco-Roman.*; Bayle, *Dict*, art. 'Zeno,' which has very copious and curious notes, or their own work, *Zeno,* by Victor Cousin, and the references there; Kant, *Kritik, sç., Die Antinomie der Reinen Vernunft.*)

ZENO of Citium, a small town in the island of Cyprus, was the founder of the sect of the Stoics. The time of his birth cannot be absolutely ascertained, or the other events of his life. He was however a contemporary of Antigonus Gonatas, king of Macedon, and died before him. Antigonus Gonatas died n.c. 240. Clinton places the birth of Zeno between n.c. 327 and 332, and his death either not completely developed or that it possessed too little originality to unite all his followers.

Chrysippus is said to have been the person who gave to the Stoical system its full development and fixed its doctrines; accordingly there was a saying if there had been no Chrysippus, there would have been no Stoics.

The Stoics made three divisions of philosophy, which Plutarch calls the Physical, Ethical, and Logical (*logipædia*), of which our word Logical is not a translation. But other Stoics made different divisions. The triple division was made by Zeno himself, as Diodorus states in his Life of Zeno, in which he has collected all the Stoical doctrines. The Logical part of the Stoical system comprehended their metaphysics. It is certain that between truth and falsehood there is nothing but true (*ἀλήθεια*); truth implied body (*φύσις*); but true was without body, and was merely in opinion. They attributed to things an absolute existence in themselves. Their system, so far as we can learn what it was, was obscure, and their metaphysical doctrines. They cultivated logic, rhetoric, and grammar. In their Physical doctrines they assumed first two principles, the Active and the Passive: the Passive was Matter (*ἔσωσα*), the first substance of the universe. The Active was God, who was one, though called by many names. The universal belief in a deity, or in many deities, they considered one of the evidences of God's existence.

All the universe, says Seneca, according to our Stoical doctrines, consists of two parts, the spiritual and the corporeal. The spirit is in motion in every part of all. The body and the soul sympathize, for each is another body. Death is the separation of the soul and the body. The Soul is a spirit (*σώματος*) that is born with us; consequently it is body, and it continues after death; still it is perishable: but the Soul of all things, which, as the animal parts, is impenetrable. As to the duration of the soul, there were different opinions: Cleanthes thought that all souls lasted to the general conflagration; Chrysippus thought the souls of the wise only lasted so long.

The Ethical doctrines of the Stoics have attracted most attention, as exhibited in the lives of distinguished Greeks and Romans. To live according to nature was the basis of their Ethical system; but by this it was not meant that a man should follow his own particular nature; he must try to submit himself to the nature of all things. This principle is the foundation of all morality; and it follows that morality is connected with philosophy. To know what is our relation to the whole of things, is to know what we ought to be and to do. This fundamental principle of their system of application is not always easy, nor did they all agree in their exposition of it. Some things were good, some bad, and some indifferent: the only good things were virtue, wisdom, justice, and temperance, and the like. The truly good was that knowledge and virtue which is sufficient in itself; he despises all that subjects to its power the rest of mankind; he feels pain, but he is not conquered by it. But the morality of the Stoics, at least in the later periods, though it rested on this apparently cold, and permitted a man to do nearly everything that he liked. Such a system, it has been well observed.
might do for the imaginary wise man of the Stoics; but it was not a system where general adoption was compatible with the existence of any actual society.

The subject of the Stoic sect is one of great extent. The Stoics, or the so-called Stoics, formed a sect that continued for four centuries, in which time the doctrines were subject to so much change that we often see little besides the name in which the professors of this sect agreed. Most of the Stoic works are lost. Two of the notable works, whose works remain, Epictetus and the emperor Marcus Aurelius, if not the most genuine specimens of the Stoic school, are certainly two of the most worthy.

(Diogenes Laertius, *Zeno; Ritter and Frelat, *Historie Philosophie Rationalistes; Diogenes Laertius, *Aurelius; Evagrius; and other articles in this work.)

ZENO (335 B.C.), emperor of the East, succeeded, in A.D. 474, the emperor Leo I. Thrax, or more correctly his own son Leo II., the younger, as will appear below. Zeno was the son of a Roman empress, Leo, but the Ioucides, a noble Isaurian, and his original name was either Arinclus or perhaps Tarasius or Tarasciscus, or more probably Trasalisus. We know nothing about his earlier life, of which however detailed accounts were probably given in the works of Eustathius of Syria, which are lost, and those of Candidus, of which only some fragments are extant. We must suppose that he was a man of great influence, especially among his warlike countrymen the Isaurians, who were known as the sect of Constantinople for in A.D. 468 the emperor Leo Thrax gave him his daughter Ariadne in marriage, evidently for the purpose of securing his influence among the Isaurians, whose assistance he wanted against the ambitious schemes of his prime minister Leo

On that occasion the son of Ruumblades adopted the Greek name of Zeno, and was created by the emperor Patriadius, and appointed commander of the imperial ill-guard and commander-in-chief of the Greek army in Asia Minor. In A.D. 469 Zeno was raised to the rank of Caesar, and he assisted the emperor in getting rid of Aspar, who was put to death in A.D. 471. Leo, being old and childless, wished to appoint Zeno his successor, but the people disliked Zeno on account of his ugliness, a reason which was not at all valid. For, although he was handsome, he was of importance among the Eastern nations, who have always liked and still like to be ruled by handsome kings. Leo consequently gave up his plan, and chose Leo, the son of Zeno and Ariadne, for his successor, in A.D. 473. The emperor Leo I., who died early in the same year, A.D. 471, was succeeded by his elder son Leo II., the younger, under the regency of his father, whom the title of Augustus was conferred on Leo Thrax; it may be that Zeno assumed that title at that time, but neither of these opinions has been established.

Zeno was created by the emperor Leo Thrax, and Leo the younger succeeded him under the regency of his father, upon whom the title of Augustus was conferred. The emperor Leo I. died early in the same year, A.D. 471, and the emperor Leo Thrax, who died in A.D. 473, was succeeded by his younger son, the emperor Leo I. The emperor Zeno was proclaimed emperor of the East, by a general of Basiliscus, who advanced upon Isauria, defeated Zeno, who retired to a castle called Constantinople. Basiliscus was made prisoner, and starved in the tower in Capadocia. Zeno was re-established by order to reward Harmacius, he made him commander-in-chief of his army. Zeno succeeded his son Basiliscus and the emperor Zeno was so aggrieved, that Zeno was compelled to get rid of him. Assisted by Illus, he succeeded in seizing Harmacius, who was put to death, and his son Basiliscus was banished, after having been deprived of his imperial dignity. Zeno continued to exert all the influence over the emperor, which he soon abused. He not only used illus to the emperor Ariadne, but against his life. Illus, being deposed from his next to the prime minister, fled to Asia and revolted against the new emperor. The emperor Zeno, who retained his power over several other rebellions broke out. Theodosius, a adherent of Basiliscus, retired after the fall of the usurper Thrac, collected a considerable force, and ravaged the environs of Constantinople. He attacked a mine, but was repulsed. Illus attacked the emperor Zeno with peace from him, in A.D. 478; but Theodoric soon forced his way, united himself with Theodore the Great, and after conquered Italy, and the emperor would perhaps have given up his throne but for the death of the emperor, which took place in A.D. 481. Zeno, to Theodoric the Great, Zeno, killed off by his anger, by creating him consul, and finally stimulated or allowed him to conquer Italy. [THEODORIC THE GREAT].

After peace had been concluded with Theodoric the Great, the emperor Zeno, Finding a man had been murdered under Marcian, the son of Anemochus, emperor of the West, and the grandson of the emperor Marcian, who married Leontia, the sister of the emperor Zeno, Marcian, intended to depose Zeno, and he took Constantius, who was his son, and surprised him, and after a desperate flight fled for refuge to a church. He was taken out by force, his head was shaven, and he was banished to a monastery at Cesarina. But he escaped, caused much trouble, and was expelled to a castle of Cyprus. He was banished to Venice, and received a pension, and that of Illus, who, as already observed, had insulted the
empress Arianne, and escaping being put to death by flying to Asia, where he placed himself at the head of an army of 70,000 men. The patrician Leontius, who was sent by Zeno against Illus, betrayed the emperor and joined the rebel. Longinus, the brother of Zeno, took the field against the Lusiaci, but was defeated and prisoners. For some time afterwards he was found in the camp of the rebels acting in concert with Illus and Leontius. The rebels then laid siege to the castle of Paphras, where the empress-dowager Verina was confined on account of her letters to Persia. Verina also joined the rebels, and as they intended to put Leontius on the throne, she adorned him with the diadem, and he was received as emperor at Antioch, in A.D. 484. Zeno then despatched a fresh army against the rebels, which was commanded by John the Hespanok and John the Scythian, two generals who have often been confounded, but who were two different persons. They defeated the rebels in A.D. 486, who took refuge in the desert. Zeno then attacked the imperial palace guard (Silentarii), Anastasius I., an army officer that had married Arianne, the widow of Zeno. It is said that Zeno died under strange circumstances, but the accounts of his death are very contradictory. In this case, the account is that Zeno was beheaded in his bed while asleep; or he died in consequence of a debauch; or he was buried alive while insensible in a fit of apoplexy; and Arianne was the author of his death. It happened however that some ecclesiastical writers, for reasons of their own, declared that Zeno never committed violence, that he never killed a woman, and that he was an upright man, but he never fell into such frightful fits of passion as Leo; he sometimes did honourable things for honour's sake, but less frequently and less with dignity and generosity. In short, he was the shadow of Leo, without his energy. Zeno was the son of Stephano, who did not understand the art of government; he was as vain as a woman, and his constant endeavours to be admired as something great made him ridiculous in the eyes of the witty Greeks.

Zenobia or Zenoia, from the coins Zenoia, SEPTIMIA, was the daughter of Ammon, an Arab chief, who possessed the southern part of Mesopotamia. By her first husband Zenoia was mother of Valens, who died at Wabarath. Her second husband was Septimius Odenathus. Odenathus was of Palmyra, a flourishing city included within the limits of the Roman empire, and dignified with the title of Metropolitana Colonia. He was at the head of some tribes which belonged to that part of the Syrian desert which surrounds Palmyra. His Roman name Septimius indicates some connection with the empire, and it is ingeniously conjectured by St. Martin that the origin of this connection is the faithful emperor named Septimius who inherited the family of Odenathus must be traced to the time of the emperor Septimius Severus. The name of the father of Odenathus was Septimius Airanes Wabarath, and Odenathus had by his first wife a son named Septimius Orodos, or Hercules, as Trebellius Polio calls him. Septimius Severus married Julia Domna, a Syrian woman of Emessa, and this circumstance, combined with his long residence in Syria, renders it probable that a connection was formed between the emperor Severus and the family of Odenathus, who, as usual in such cases, would adopt the name of their Roman patron. In the year A.D. 244, after the assassination of the younger Gordian, Philip, called the Arabian, was proclaimed emperor, and on leaving Syria for Rome he intruded the government of Syria to his brother Priscus. The bad administration of Priscus caused a rebellion in Syria, and Septimius, a niece without the royal house which had reigned at or possessed Emessa, was proclaimed emperor. Jotapius was defeated by the imperial troops and lost his life, but Philip was assassinated before the news could reach him. Other usurpers arose in Syria, but Septimius successfully withstood all attempts. In the year 251 Septimius Airanes was prince of Palmyra, and his son Odenathus was general. On the death of Airanes, Odenathus succeeded to the principality of Palmyra. The year 254 was the death of Septimius Zeno, and it is not certain, but it was before A.D. 256. In A.D. 256 Marcus, to whom Trebellius Polio calls Cyriades, left Antioch with a large sum of money, and betook himself to Sapor, king of Persia. He persuaded Sapor and Odenathus to an invasion of Syria, in which attempt the latter was taken prisoner. He enjoyed his dignity for about a year, having been assassinated, according to Trebellius Polio, while Valerian was on his march to the Persian war. It was Sapor's design to anticipate Valerian by invading Syria, but he was defeated at Ctesiphon. He had the head of Odenathus, assassinated by his old ally Odenathus. But after the surrender of Valerian to Sapor, Odenathus sent costly presents to the Persian king, in order to conciliate him; the presents were rejected with contempt, and Odenathus was commanded to bring Valerian to Persia by order of the emperor. He died during his march, and while the Roman troops were retreating on all sides in the confusion which followed the capture of Valerian, he alone opposed the progress of the Persian armies. The Persians had entered both Syria and Cilicia, and Odenathus was at Antioch. He was a bold commander, and the Arabs of the desert, and some few Romans who joined him, attempted to cut off the retreat of Sapor, in which he was aided by Balista, the Roman general, who made a successful resistance in Cilicia. His wife Zenobia also accompanied him in this campaign, and he ordered her to retreat; but at the passage of the Euphrates he sustained a defeat and lost much of his baggage. He was followed by Odenathus through Mesopotamia, again defeated, and with the Ctesiphon, to the Tigris. If Odenathus had besieged Ctesiphon, it appears that it was not successful.

About this time Odenathus assumed the kingly title, and it is probable that he was considered emperor in the East. Gallienus, who bore a like name to his father's capture, A.D. 266, was too indolent to attempt to maintain his authority. The Roman army in Syria and Egypt proclaimed Macrianus emperor, who associated with himself in the empire his two sons Quietus and Macrianus. Quietus was in Syria, where he was opposed by Aureolus, who had also risen against Gallienus, and totally defeated. Upon this Aureolus was received by Galienius into partnership in the empire, and he followed him to the East to the partition of Macrianus. Odenathus, seeing what turn things had taken, entered Syria, upon which Balista, who had quarrelled with Quietus, murdered him and delivered up to Odenathus the town of Emessa, in which Quietus and Macrianus were then both. It is said that Odenathus claimed himself emperor, but he was defeated by Odenathus and lost his life. About this time probably (A.D. 283?) Odenathus was associated by Galienus in the empire, and received the title of Augustus. A quarrel was broken out between the partisans of Macrianus. Odenathus now undertook a second war against the Persians, to avenge the cause of Valerian; he made many prisoners, whom he sent to Gaius, and caused them to be hanged, as a punishment for being killed by the bravery of another. Odenathus again besieged Ctesiphon, but without any result. On leaving Ctesiphon he marched into Cappadocia to oppose the Scythians, who were ravaging that part of Asia Minor. Odenathus was assassinated at Emessa in Syria with his son Orodos, by a relation named Macrianus, A.D. 267, the conspirators were put to death by the soldiers of Odenathus, and his wife Zenobia succeeded to his power.

The events of the life of Odenathus are confusedly told, yet the main facts may probably be received as true. He
lous, king of Macedon, which was from a.c. 413 until n.c. 389; and Harduin and others are therefore probably incorrect in fixing upon Herculea in Lucania, in Italy, as the birth-place of Zeuxis; for that city was not founded until after the destruction of Siris, a.c. 433. (Diodorus Siculus, xiii. 59, 60.) From this complaint of Apelleus, who lived at Athens, Zeuxis must also have been early in that city; and he was most likely a native of one of the Hercleas in Greece, and, from his connection with Archelaus, probably Hercules Lyncestis in Macedonia. Herodes Atticus says Herculea in Lucania to be the birthplace of Zeuxis, from the circumstance of his being commissioned to paint a picture by the Crotontians—a very insufficient reason. Zeuxis, when he had made himself rich by his profession, and must accordingly have been somewhat advanced in years, gave away some of his works, and Archelaus was then living, for he presented a picture of the god Pan to that king. Zeuxis lived also some time at Ephesus, and Tzetzes, an indifferent authority, calls him a native of that city. Lucian tells us that the greatest painter of his time: he was immediately preceded by Apollodorus of Athens, whom he surpassed; and he was immediately followed by Parrhasius of Ephesus, who surpassed him. The peculiar excellence of Zeuxis was in the execution of things amiss and ancient times; as he drew well and in a grand style, and the beauty and grandeur of his forms were so predominant, that he was said by Aristotle to have failed in expressing mind. Aristotle adds that he was in this respect much surpassed by his younger contemporaries, Thamyris, who practised his art in the next century. Quintilian says that Zeuxis followed Homer, who loved powerful forms even in women; he likewise noticed his excellence in light and shade. Cicero also speaks of the fine forms of Zeuxis. That he was excellent in light and shade and colour is evident from the complaint of Apollodorus, that Zeuxis had robbed him of his art: effective colouring and light and shade were the peculiar excellences of Apollodorus. With these excellences Zeuxis combined a dramatic effect of composition, and the wonderful thing was being able to draw and to paint pictures as Tirion. Other famous works by him were—Jupiter in the midst of the assembly of the Gods; Penelope beseeching the absence of her husband; Menelaus mourning over the fate of Agamemnon; a Massys bound, in the temple of Concord at Rome in Pliny's time; an Athlete, under which he wrote the line—"It is easier to find fault than to state,"—which, according to Plutarch, Apollodorus wrote upon some of his pictures; and a Cupid crowned with roses, that Ephesus was proud of. This picture is noticed by Aristophanes in the comedy of the 'Acharnenses,' but the painter's name is not mentioned; it is however ascribed to the scholar who is his. As the comedy was acted as early as the third year of the Olympiad (426), it is evident from the scholar to ascribe the picture in question to Zeuxis, as he cannot have painted so soon; but from what has been said above it is pretty evident that Zeuxis was a man of mature years in n.c. 426, and, as we have seen, had amassed a fortune within 27 years of this date, for he presented a picture of Pan to Archelaus, who died in a.c. 388. Zeuxis had previously executed several works for Archelaus in his palace at Pella, for which the king, says Pliny, paid him 400 minas, 1250, according to Horn. If, therefore, it be granted, as to the later part of the Olympiad (355), the year in which Isocrates delivered his oration to 'Aphrodite' (on the exchange of property), in which he praises Zeuxis, for, according to the Greek custom, he would not have done it had it been true, then still another, no less an authority than Vitruvius (book x., p. 632) relates, from Verris, that he died through laughing excessively at the picture of an old woman which he had made, but this is perhaps a mere fiction: there is no other notice of such a disaster. Zeuxis is represented another, but to the name of its Romanizing, it is a very poor piece of his reputation and entitlement of his wealth; he used to wear a mantle with his name woven in letters of gold on the border. To balance this weakness there are two or three anecdotes of an opposite character, which show that he had no want of penetration. Plutarch relates a story,
that upon an occasion when in his company a painter of the
ame of Agastarchus boasted of the great facility and
rapidity with which he painted, Zeuxis quietly remarked,
that he took a long time to paint anything. And Pliny
records how he reproved a certain Megabyzus, a high
priced painter, upon his boasting to be a rival of his own,
and asked if he thought to be painted or a god. But now
the painter conversed so very ignorantly about pictures,
that some lads who were grinding colours were forced to
laugh, upon which Zeuxis observed to him—As long as you
were silent, these boys were admiring you, wondering at your
great skill; and the number of the days is the less!—but now
that you have ventured to discourse about the arts, of which
you have no knowledge, they are laughing at you.'
Plutarch relates this story of Apelles and Megabyzus, and
Pliny relates it of Apelles and Alexander. Zeuxis, proba-
ably, was the principal successor of the great Parmen-
sius; Zeuxis painted some grapes which are said to have
deceived birds, but Parrhasius painted a curtain which de-
ceived Zeuxis himself, who accordingly confessed himself
beaten; Zeuxis also painted a boy carrying some grapes,
which likewise deceived the birds; but in this instance, to
the dissatisfaction of the painter, who justly observed, that
if the boy had been as well painted as the grapes, the birds
would have feared to approach them. Though these
stories in themselves are valueless, the fact that such stories
should have been circulating in antient times is of
considerable interest, as it shows that the antients believed
that exact imitation could be accomplished in colours, a
result they could only have arrived at by the evidence of the
eyes, for it is impossible to know by the senses the true
surface of objects; that, such productions at more than their due value, which
is evident from the fact that there is scarcely a passage in
antient authors in which mere beauty of execution and exact
fidelity of imitation are praised, if we except one or two
instances in which the painter is considered as a poet, and
principally of all the antient writers speaking of the arts.
Cicero states that Zeuxis used only four colours, but this
is probably an error, or he may mean in his caricatures,
in which four are all that are necessary. The same writer
names a painting of a little dog exactly resembling a

ame, of Aglaophon, and of Apelles are in different styles,
yet they are all three perfect in their respective styles. Zeuxis painted also pictures in white or mere chiaroscuro,
that is, in light and shade, what the Greeks termed monoch-
romas; such subjects are very common now.
It is remarkable that Pausanias does not mention the
name of Zeuxis, and we may infer from this that Zeuxis
painted easel pictures only, or upon tablæa, wooden panels

(πίνακας), which, from their perishable nature and facility of
movement, were probably the most artistic of art works.
The more exact knowledge of these panels, the greater the risk
that his works will perish, as they are better worth removal. Few of the great
painters of Greece painted upon walls: Apelles never did,
and the only pictures we have been described of were those
delphian pictures on columns, which were inserted in the
walls; on this subject see Raoul Rochette, 'Sur l'emploi de la Peinture,' &c.

[Pliny, Hist. Nat., xxxv, 9, 36; Lucian, Zeuxis or An-
ticibus; Quintilian, xii, 10, 3; Cicero, De Jovent., ii, 1;
Bretius, 18; De Ora, iii, 7; Valerius Maximus, iii, 7, 3;
Aelian, ii, 2; iv, 12; xiv and 47; Tzetzes, Chil. viii,

ZIEGLER, FRIEDRICH WILHELM, a popular actor
and dramatic writer of Germany, was born at Brunswick
in 1760. His fine person, and his great talents as an actor
made him the favourite of his time. It is said he was the
actor for the court theatre of Vienna, and the Emperor at
his own expense sent him to the best German theatres for
the purpose of studying and cultivating his art, and afterwards
appointed him to the court theatre of Vienna, where
Zeuxis, as a painter and poet, may be considered a
plain title for the place he held. He was never satisfied with his fame as an actor, but he endeavoured to
obtain the higher reputation of a dramatic author. His
attempts were crowned with great success, and he became
one of the most popular and prolific writers of the day. His
plays and dramas, all in prose, were performed at Vienna and in nearly all the
towns of Southern Germany, where they enjoyed such
popularity as those of Iffland and Kotzebue. Invention,
situation, and effect were generally very happily combined
in his plays, and he showed a great practical knowledge of theatrical affairs; owing to these circumstances, some of
his plays, such as 'Parteienwuth' and 'Die vier Tempera-
mente,' still continue to be acted, although the language is
rather obsolete. In 1798, when Kotzebue came to Vienna
his plays were so universally beloved, that Ziegler felt an
inward and right spirit, and a sense of being able to do
so much an opposition to him, that he quit Vienna after
two years. As Ziegler was engaged in the service of the
imperial court, he frequently allowed himself to be made
use of for political purposes, partly by writing plays with
a political and tending to abuse of the Spanish and Austrian
allegions. A collection of his dramatic works, in 3 vols.
8vo., appeared at Vienna, 1791-94. A more complete col-
lection of Ziegler's 'Sämtliche Dramatische Werke,' in 13
vols. 8vo., appeared at Vienna in 1821. He made also
several attempts at the translation of the heroic dramas,
but his success was small, as he possessed little philosophi-
cal knowledge, whereas his aesthetic works are very con-
 fused and almost worthless. His principal works in this
respect are,—1, 'Zergliederung von Hamlet's Charact
psychology and Ethicus,' Wien, 1803, 8vo.; 2, 'Die Dramatische Schauspielkunst
in ihrem ganzen Umfange,' Wien, 1821, 8vo.; 3, 'Der innere und ausserre Mensch in Beziehung auf die bildenden Künste,' Wien, 1823.
Die Mondschein,' in 2 vols. 8vo. In the year 1821 Ziegler left the stage, and
received a pension given to him for the remainder of his life, which he spent principally at Presburg. He died at Vienna,
on the 21st of September, 1827.

ZIMBACH, Christian—Lexikon, Bibliothek der
schönen Wissenschaften, unter Ziegler.'
ZIMAPAN. [MEXICAN STATES]
ZIMB, an insect translated hornet in Scripture (Exod.
chap. xxviii., ver. 25; Deut. vii. 20; Joshua xxiv. 12.)
It is remarkable that this name is, in Hebrew, and of
the same meaning as Zimm, the name of a city, Zunil, of
the Indians, in Peten, Guatemala, in which country the
buzzing noise, the account which Bruce has given of the
zimb, or dog-fly, of Abyssinia, offers such striking analogies
to the insect specifically termed tsirah, and included in the
more general term zebub of the Hebrew Scriptures, that
we cannot but lean to the identification of the two.
It is difficult to conceive that Isaiah could have had in
view any other insect when he says—'The Lord shall hiss for the
fly that is in the uttermost part of the rivers of Egypt.' (Isaiah vii. 18.) The original word rendered fly in the English
version of the Bible has the sound of vizebub, which is the
proper name of a particular fly in Geer, and was the same in Hebrew.
The following is the substance of the account which Bruce
gives of the Abyssinian zimb. This insect had not pre-
vious to his time, been described; it does not measure
very little larger than a bee, of a thicker proportion, and
has wings, which are broader than those of a bee, placed
separate, like those of a fly; they are of fine gauze, without
colour or spot upon them. The head is large; the upper
jaw or lip is sharp, and has at its end, in a strong
pointed hair, of about a quarter of an inch long; the lower
jaw has two of these pointed hairs, and the penel of hairs
when joined together makes a resistance to the finger
nearly equal to that of a hog's bristle. Its legs are serrated
on the inside, and the feathers covered with bristly hair
down . . . . He has no sting, though he seems to me
rather of the bee kind; but his motion is more rapid and
sudden than that of the bee, and resembles that of the
gnat fly in England. There is something peculiar in the sound
of the buzz of this insect, which induces me to believe it proceeds, at least in part,
from a vibration made with the three hairs at its snout.
'As soon as this plague appears, and their buzzing
is heard, all the cattle forsake their stall, and are
covered with fat and are worn out with fatigue, fright,
and hunger. No remedy remains but to leave the black
earth [where they breed] and hasten down to the sands of
Atbara, and there they remain while the rains last, this
cruel enemy never daring to pursue them: the tribe is immense as is his strength, and his body covered
with a thick skin defended with strong hair, yet even the
camel is not able to sustain the violent punctures the fly
makes with his pointed proboscis. He must lose no time
in removing to the sands of Atbara, and therefore at

Vol. XXVII.—G 3
tacked by this fly, his body, head, and legs break out into large bosses, which swell, break, and putrefy, to the certain destruction of the creature. Even the elephant and rhinoceros, who, by reason of their enormous bulk and the vast quantity of food and water which they require daily, cannot shift to desert and dry places as the season may require, are obliged to roll themselves in mud and mire, which constantly coats them over with a kind of armour, and so to stand their ground against this winged assassin; yet I have seen some of these tubeceles upon almost every elephant and rhinoceros that I have seen, and attribute them to this cause. All the inhabitants of the sea-coast of Mr. Cuvier, of Cape Gad's, and the coast of the Red Sea, are obliged to put themselves in motion and remove to the next sand in the beginning of the rainy season, to prevent all their stock of cattle being destroyed. This is not a partial emigration; the inhabitants of all the islands of the Indian Ocean were thus called in reverse of the flood. These were the Shepherds, leading a wandering life and preserving their immense herds of cattle by conducting them into the sands beyond the limits of the black earth, and bringing them back again when the danger from this insect would be over. Nor has the history of the plagues which God brought upon Pharaoh by the hands of Moses, without stopping a moment to consider a singularity—a very principal one—which attended this plague of the fly. It was not till this time, and by means of this insect, that the Lord said he would destroy Pharaoh and the Egyptians. And it would seem that then a law was given to them that fixed the limits of their habitation. It is well known that the land of Goshen or Geshen, the possession of the Israelites, was a land of pasture, which was not filled or seven, because it was not overflowed by the Nile. But the land overflowed by the Nile was the black earth of the valley of Egypt, and it was here that God confined the flies; for he says, it shall be a sign of this separation of the people, that not one fly should be seen in the land of Egypt. In the foregoeing, that land which is now a kind of soil has ever since been the refuge of all cattle emigrating from the black earth to the lower part of Athbara.

If the fly that is in the uttermost parts of the rivers of Egypt, which is held forth in Isaiah as an agent for the punishment of iniquity, is (as we have shown there is every probability of its being) the insect now under consideration, it would appear that the zimb was not then, any more than at the present day, a native of Palestine, but that swarms of them were drawn from Egypt for the execution of a special purpose. From Bruce's graphic description of the habits and appearance of the zimb, we are irresistibly led to connect it with some of the Cestrize. Laterrell, Mr. Hope, and others, who have already mentioned the zimb being subject to the attacks of the Cestrize, and Mr. Hope, stated a few years ago, to the Entomological Society an account of a larva of one of these insects which attacks the rhinoceros. As this portion of Bruce's narrative (relating to the habits and the effects produced by these flies) is much ridiculed and long regarded as particularly unworthy of belief, we may add that, in addition to the facts stated by Laterrell and Mr. Hope, strong corroborative testimony may also be found in the works of more recent African travellers, although not bearing directly upon the actual zimb. — Notwithstanding our fatigue, no rest could we obtain. The buzz from the insects was like the singing of birds; the men and horses groaned with anguish, &c. &c.

If I do not think our animals could have borne such another night, the zimb would have continued all the time Bruce had written on the subject. He told us that hogs and cows were its principal victims, but that he had heard of armies being destroyed by this terrible scourge. (Clarke's 'Travels,' 2nd part, sec. ii., p. 65.)

The Cestrize were probably only different pronunciations of the same term he-tand, as this fly is called both by Moses and Joshua. Mr. Sir Clarke, in the 9th volume of the 'Linnean Transactions,' part ii., 1843, refers the fly alluded to by Moses (as he to his great damage) to Asilus Cestrise. A few remarks upon Bruce's figure, that it has no resemblance to the genus of flies the Culicerebra, but is rather, though with something fictitious about it, allied to the genus Schoenus, or perhaps Tubanise, both of which genera are certain killed in their attacks on cattle.

There can be no doubt that the zimbop is a perfectly distinct insect from any of the modern Cestrize. Aristotle describes it not merely as a blood-sucker, 'Vitaria TUBANUS,' but also as a parasite upon a strong proboscis (lib. iv., c. 7). He observes, likewise, that it is produced from an animal inhabiting the waters, in the vicinity of which it chiefly abounds in; i.e., in Egypt. (Hist. Anim., lib. vi., c. 38.) This near the Nile, or rather the Nile, and the coast of the Red Sea, where the flies are confided on this fly is, one of the largest: it has a stiff and long proboscis (measuring proboscis, and emits a certain humane and harsh sound. Virgil's account, as far as the source is concerned, is similar. Now the modern Cestrize is from being a blood-sucker, furnished with a strong proboscis, has scarcely any mouth; and it especially since the vicinity of water, to which cattle fly for refuge. Here it is more probably related to Bruce's zimb which represents a new genus, as Bruce's zimb is found in the neighbourhood of rivers, and belongs probably to Pagonik or to Nemat ostrica.' (See Kyby of Spence's 'Intr.'

ZIMMERMANN, JOHANN GEORG VON, was born on the 13th of December, 1728, at Brugs, a small town in the German part of the canton of Bern. He belonged to a distinguished family, especially on his mother's side, and as she was a native of the French part of the canton of Bern, Zimmermann acquired from his childhood a facility in French and good knowledge of English. His education was conducted in the house of his parents up to his fourteenth year, when he went to Bern to prepare himself for the university. In 1747 he went to Gottingen, to study medicine, and here he was received by Haler. Zimmermann, the kindest man that ever met an acquaintance with English literature, for which he had always a great partiality. Love of study was so great, that he scarcely ever took any relaxation; and he thus laid the foundation of science by which he suffered all through life. The death of his elder brother, GTammer, distressed him. 'I here lead the life of a man who is destined to die even after his death.' The first symptoms of melancholy appeared while he was yet at Gottingen. When he returned to Gottingen, he wrote his 'Dissertation Physiologicae de Irritabilitate' (Gottingen, 1751, 4vo.), by which he acquired considerable reputation as a theoretical writer on medicine, both on account of the independence of his judgment and the soundness of his arguments. This little work is still held in high esteem. It was translated into Italian by P. Gian Vincento Patrizi (Naples, 1756, 8vo.). After leaving Gottingen he spent a few months in Holland and at Paris, and then returned to Bern, where he commenced his career of a physician with great success. Shortly after, because of ill health he came from Gottingen to see his friends at Bern, and also for the recovery of his health, and his native place had such
ZIM 779 ZIM

charm for him, that he resolved not to return to Hanover. Zimmermann was commissioned to fetch Haller's family from Göttingen, and not long after he married a relation of his (Sztadt physicus), at Brugg became vacant, and Zimmermann, who had already acquired great reputation as a physician, was prevailed upon to accept it on account of his property and family connections he had at Brugg. His practice there was not of small importance: he was, for no physician surpassed him in the quick perception of the nature of disease and the remedies required to remove it; patients came from all parts of Switzerland and from the adjoining countries; and although he was short of public opinion, it was not so to several of the courts of Germany, where his advice was requested by the waters of Pyrmont. But in a short time he found that Pyrmont, instead of being a place of rest for him, was a much more busy place than Hanover, for persons flocked thither in numbers, for the treatment of the best physicians in Hanover.

In 1770 his wife died, and he himself was in a state of constant suffering from internal disease, which induced him the year after to go to Berlin for the purpose of submitting to a dangerous operation. He remained at Berlin for five months, and the advice and skill of the most distinguished men of that capital. He was also introduced to Freideric the Great, with whom he had a long conversation. On his return to Hanover he felt in good spirits, and as he had got rid of the cause of his suffering, he said he was going forward with his great professional exertions brought on a return of his old complaint, and in its train came his former depression of spirits, which was increased by the death of his daughter. He had now only a son left, and this son in ill-health, and Mercier, in a state of perfect insensibility. The friends of Zimmermann, who pitied his situation, prevailed upon him to marry again: the influence which his young wife exercised over him promised to be most beneficial; he returned to his practice, his cheerfulness increased, and he became popular in social circles. The fruit of this happy period was the working out and completion of his great work on Solitude ('Ueber die Einsamkeit'), which appeared at Leipzig in 1797. It is divided into five books, in which he meditates on the subject of the latter part of human life, the first book on the last days of old age, and the second and third on bordering on the last stage of life. This work, which is the most matured of all his productions, was soon translated into all the languages of Europe, and became as popular in foreign countries as in Germany. The English translation, under the title 'Solitude considered with respect to its influence on the mind and heart' (London, 1797, 8vo.), was made from the French translation of J. B. Mercier, which however is only an abridgment of the original; for Mercier had not the boldness to lay before the French public all the important disclosures which the work contains. This book obtained such a vogue that the author friends and admirers in all parts of Europe. The empress Catherine II. of Russia sent him a magnificent present, accompanied by a letter in which she thanked him for the salutary prescriptions he had given to her son, and offered him the post of her private physician. On his declining to go to Russia, the empress requested him to recommend a number of young physicians who were willing to settle in her dominions. This request was readily complied with, and Zimmermann was thanked, and received the order of St. Vladimir as a reward. In 1786, when Freideric the Great was attacked by his last illness, he wrote two letters to Zimmermann to invite him to come to Potsdam. On his arrival there, Zimmermann discovered that the king's case was hopeless, and he refused to prescribe any powerful medicine. His visit to Potsdam was the turning point in his life: until then he had been the favourite of the great, and had had many honourable offers made to him from various parts of Europe, but he had not resolution enough to accept them, or they were not to his taste. At last however the honourable post of physician to his Britannio majesty at Hanover, and the title of suile councilor, were offered to him, through the influence of a friend. This offer seemed to satisfy his wishes, and in 1786 he went to Hanover. But the world in which he now lived was as little calculated to give him happiness as that at Brugg. The jealousy of many, and the caprices of his patients, made his situation wretched; and his own dignity too much, and had too just a notion of the duties of a physician to determine the number of his visits and their duration by anything else than the nature of the disease. Those to whom he had made himself obnoxious by such straight forward conduct, did not of course contribute to make his residence at Hanover pleasant. But notwithstanding this, there was at that time no physician in all Northern Germany who enjoyed such unbounded confidence as Zimmermann, and it is clear that he had little time left to indulge in his hypochondriac disposition. During this period of uninterrupted activity in his profession, his only recreation was reading and making notes. He was a patron of the arts, was remarkable for his great ambition, and his love of solitude, and while he was ever longing for the intellectual employment which he should observe, render it still a work of child, to enjoy the pleasures which he might have had. His hypochondriac disposition was thus gradually developed, and increased his love of solitude. He avoided society as much as he could, and spent all his leisure hours in readings and in reflecting upon the duties of his profession. It is remarkable that even during the strongest attacks of hypochondrias Zimmermann appeared to be so much altered. He avoided society as much as he could, and spent all his leisure hours in readings and in reflecting upon the duties of his profession. contested attacks on men of unblemished character, and Zimmermann charged them with things which had no existence except in his own imagination. Truth itself seemed no longer to be sacred to him, and various calumny reports respecting the private life of Frederick the Great and other eminent men were set forth as new discoveries, and that in so coarse a manner as to offend the good feeling of the public. The cause of this change in his conduct must be looked for in his discontented disposition, his desire to show the world a new sphere for his talents, and he was not fitted—politics and contemporary history. The peculiar state of his own mind prevented his gaining a clear perception of things, and made him see in the political changes of the time nothing but conspiracies to upset princes and all social order. The Revolution and, especially on the part of the freethinker Dr. Bahrdt and A. Hoffmann, only increased those feelings. He now devoted all his time to the combating of the monsters which his own imagination raised up, with the exception of two hours every day, which he gave to his patients. His diseased imagination represented to him Jacobins, Illuminati, and the promoters of improvements of every kind, as persons animated by the same evil spirit, and he denounced all as criminals who ought to be put to death by the hangman. In order to secure the assurance of all governments against them, he drew up a memorial, which he sent to the emperor Leopold, and which bore the following title: 'Über den Wahnsinn und gegen die aufgestiegenen Häupter gegen die Mordbremder, die uns aufführen wollen, und gegen die Untergrabung und Vernichtung der christlichen Religion und der Fürstengewalt.' It consisted of 370 quarto pages. The emperor intended to place it before the princes at Regensburg, and to call upon the princes of the empire to put an end to the proceedings of the Illuminati. But the death of the emperor, who had testified his gratitude to Zimmermann by a handsome present, prevented this plan being carried into effect. Zimmermann, however, continued his exertions till the year 1704, when his physical as well as mental powers began to decline, and he was obliged to give up all his occupations. His melancholy rose to a deplorable height. The French revolution was making rapid progress, and he fancied that he saw a last chance of raising himself, and going to put him to a cruel death as an aristocrat; he even thought of taking to flight, and as his physician believed that a chance of place might be beneficial, Zimmermann went to Eutin in Holstein. But no means were of avail, and, after three or four months, he returned to Hanover in a worse condition than he had left it. His fear of his enemies was at last increased by the dread of poverty and starvation, a monomania which the most subtle tricks of the cunning tricksters were unable to destroy. Wherever he went he fancied that he was diffusing the impieties of the plagues; in short his mind was completely deranged, and after months of severe suffering, both real and imaginary, he died on the 7th of October, 1795, in the sixty-seventh year of his age.

Zimmermann was one of the most remarkable men of the last century, both as a physician and a philosoper. He possessed an inexhaustible imagination, great sagacity and judgment, and most extensive knowledge not only of medicine, but also of philosophical history, and the whole range of antient and modern literature. The great works which he wrote previous to 1760 are masterly productions of their kind, and, as far as their style and language are concerned, they are still classical, with the exception of a few passages in which French animadversions are thrown into the spirit of the German language. During the latter period of his life his mind was not sound: his nervous sensibility and his hypochondriac disposition had ruined his mental powers, and for all he did during that period he never had any wish to be of any use to the world. Besides the works which we have already noticed, and a number of essays in literary and scientific journals, the following deserve to be mentioned:—1. 'Leben des Herrn von Linsbach,' 1755, 8vo. 2. 'Vertheidigung Friedrichs des Grossen gegen die Gegenen von Mirabeau,' 1763, 8vo. 3. 'Versuch in amuthndigen und lehrreichen Erzahlungen, lauterlichen Einfelln und Philosophischen Remarcken über allerlei Gegenstücke,' Göttingen, 1790, 8vo.; this is a collection of essays which Zimmermann had contributed from time to time to a Hanoverian periodical, and were published in one volume by an anonymous editor; 4. 'Zerstreute Blatter von fremden Inhalts,' edited by a friend of Zimmermann after his death (1790, 8vo.); 5. 'Die Zersetzungs von Linsbach, 1765, 8vo.; 6. A. Zimmermann: 'Krankengeschichte, ein Biographisches Fragment,' Hanover, 1796, 8vo.; Zimmermann's 'Verhältniss mit der Katerina Catharina II., und mit dem Herrn Winckel, zu Leipzig, 1803, 8vo.; 7. 'Zimmermann's Briefe an einige seiner Freunde in der Schweiz, Aarau, 1803, 8vo. ZIMMERMANN, E. A. W. [Ueber.] Zin. This metal, in commerce frequently called Spelter, was first used by the ancients. A specimen of the metal, occurring in zincite, in the sixteenth century, under the name of Zinodium. It does not occur in the native state, but is obtained from its ores, which are chiefly the sulphurated carbonizine zinc, and contained in the zincite the operation by which it is produced from its ores is called distillation by descent. The compound zinc is 6-862; and is forged, 7-295. It undergoes little alteration, even under the combined operation of air and moisture, at constant temperatures. When heated between about the temperature of boiling water and 300° Fahr., it becomes malleable and ductile, so that it is rolled into sheets drawn into wire. It fuses at 773° Fahr., according to Dauvill.; and when cautiously cooled, crystallises, and is a particular. Exposed to a white heat, or the contact of air, it sublimes and is lost. We shall now notice the various ores of zinc, peculiar that two only of them, namely, the sulphuret and carbonate, are usually employed as such. Substances Occurring Crystalized as massive. Primary form the cube. Cleavage parallel to the planes of the rhombo-dodecahedron. Fracture conchoidal. Hardness, scratches carbonate of lime, and is scratched by phosphate of lime. Rather brittle. Color white, and various shades of yellow, green, red, and black. Streak varying with the color from white to reddish brown. Lustre adamantine. Transparent: translucent: opaque. Specific gravity 4-07. Massive Varieties.—Amorphous: crystallized, granular, compact, globular, botryoidal, reniform, chalcedonic, fibrous. Before the blowpipe does not melt per se; but when heated on charcoal, fumes of oxide of zinc form a white coating upon it. When nearly or quite pure, forms colourless solution in nitric acid with the separation of sulphur. Found in great abundance in many countries, both primary and secondary formations, and both in veins and beds. It is abundant in Cornwall and several of the northern counties of England; is also found in New Jersey, North America. Large quantities of the ore of zinc are met with and worked in Germany; they occur also in various other parts of the earth.

Some varieties contain small portions of iron and carbon.
Z I N

Oxysulphuret of Zinc; Voltzite.—Occurs in the form of small hemispheres, divisible into thin layers. Fracture conchoidal, irregular. Hardness 4-5. Colour yellowish red, interspersed with brown bands. Lustre pearly on the natural layers, but vitreous or resinous in the other directions. Slightly translucent; opaque. Specific gravity 3-06. Occurs in Cornwall and at Roziers, department of Puy de Dorne, France.

Carbonate of Zinc; Calamine.—Occurs crystallized and massive. Primary form a rhomboid. Cleavage parallel to the primary planes. Fracture uneven, conchoidal. Hardness, scratches flour-spar, but is scratched by apatite. Colour white, yellowish white, grey, brown, and green. Streak white. Lustre vitreous. Translucent. Opake. Specific gravity 4-422.

Massive Varieties.—Amorphous; structure granular, compact, reniform, botryoidal, stalactitic; fibrous. This ore occurs rather abundantly, and is found both in veins and beds, in various parts of England, France, and in America.

Soluble, with the extrication of carbonic acid gas, in acids.

Hydrous Carbonate of Zinc; Hydrous Calamine.—Occurs usually massive or enclosing other minerals. Texture fine-grained and close. Hardness 2 to 2-5. Colour white or greyish or yellowish white. Dull; opaque. Specific gravity 3-584 to 3-598. It frequently accompanies the preceding species.

Soluble in acids with the extrication of carbonic acid gas.

100-2

Before the blow-pipe yields water, but no carbonic acid; becomes milk-white, and melts into a clear colourless glass. Soluble without effervescence in nitric or hydrochloric acid, and slowly in sulphuric acid.

Found hitherto only in the calamine-mines of Altenberg, near Aix-la-Chapelle.

It has not been perfectly analyzed, but consists of oxide of zinc, a little cadmium, an earth, and much water, probably combined with phosphoric acid.

Siliicate of Zinc; Willemite.—Occurs crystallized and massive. Primary form an obtuse rhomboid. Cleavage easy, in a direction perpendicular to the axis. Transverse fracture conchoidal. Hardness, readily scratches glass and phosphate of lime; is scratched by the knife. Colour usually yellow, brownish, or reddish yellow, sometimes white and transparent. Specific gravity 4-18.

Before the blow-pipe, the crystals partly lose their transparency; with borax, a globule is obtained, which is transparent, with a small nucleus of silica floating in it.

Found at Moresnet, Aix-la-Chapelle.

It yielded by analysis:

Hydrous Siliicate of Zinc; Smithsonite; Electric Calamine.—Occurs crystallized in attached and globular or botryoidal aggregations of crystals. Primary form a right rhombic prism. Cleavage parallel to the lateral planes. Fracture conchoidal, uneven. Hardness, scratches flour-spar, and is scratched by felspars. Brittle. Colour white, blue, green, yellow, and brown. Streak white. Becomes electric by heat. Lustre vitreous. Transparent; translucent. Specific gravity 3-373. When heated in a glass tube yields water, and becomes milk-white. Heated before the blow-pipe with borax, it dissolves into a colourless glass, which does not become milky on cooling.

When powdered and heated in hydrochloric acid, the oxide of zinc is dissolved, and the silica gelatinizes on cooling.

Found at Matlock in Derbyshire, and other parts of England; in Scotland, Germany, and many other parts of Europe.

Aluminate of Zinc; Automalite. [Garnite.]

Oxide of Zinc and Oxide of Manganese; Red Oxide of Zinc; Spardalite.—Occurs in embedded small nodules and massive. Cleavage parallel to all the planes of a regular hexagonal prism. Brittle. Colour white. Hardness 4 to 4-5, easily scratched by the knife. Brittle. Colour bright red. Streak orange-yellow. Lustre adamantine. Transparent. Specific gravity 5-4 to 5-5.

Massive Varieties.—Amorphous, structure crystalline, granular.

Before the blow-pipe insufible per se; but with borax gives a yellow transparent glass. In nitric acid dissolves without effervescence.

Found only in New Jersey, North America.

The quartz is a mere accidental admixture.

Bi-selenuret of Zinc and Protosulphuret of Mercury;
The distinguishing characters of Zingiberaceae are—first, the structure of the seed, in which a fleshy body is interposed between the embryo and the albumen, entirely enveloping the former. This body is called vitellus by Brown, and is the remains of the innermost integument of the ovule, which is unab sorbed during the progress of the development. A true stamen contains the 2-celled anthers; and with this structure is combined decidedly aromatic properties. But the distinction between Marantaceae and Zingiberaceae depends, as pointed out by Lindley, on more important considerations than these. In Zingiberaceae, he says, the brown has not only the stamen is always placed opposite the labellum, or anterior division of the inner series of the corolla, and proceeds from the base of the posterior outer division; while the sterile stamens, when they occur, are posterior and on the labellum. But in Marantaceae the fertile stamen is on one side of the labellum, occupying the place of one of the lateral sterile stamens of Zingiberaceae. This peculiarity of arrangement indicates a higher degree of irregularity in stamen-number, and also extends to the other parts of the flower. The suppression of parts takes place in the latter in a symmetrical manner; the two posterior divisions of the inner series of the perianth are occasionally absent, consequently the suppression of the anterior stamen also. In Marantaceae, on the contrary, the suppression of organs takes place with so much irregularity, that the relation which the various parts bear to each other is not always apparent: instead of the central stamen being perfect, while those lateral ones are abortive, as in Zingiberaceae and most Orchidaceae, or of the central stamen being abortive and the two lateral ones perfect, as in some Orchidaceae, it is the central and one lateral one that are suppressed in Marantaceae. Taking Zingiberaceae and Marantaceae together, they are nearly alike as Musaceae, especially in the character of their leaves; but all Musaceae have either five or six stamens, with a calyx and corolla alike. With Irisaceae these orders also agree in their inferior florescence, and the tripartite division of their stamens, but the left sterile or deform character of these organs in Zingiberaceae and Marantaceae distinguishes them. Their aborted stamens ally them with Orchidaceae, from which however they differ in the absence of the cohesion of stamens and style.

The following genera belong to this order:

1. *Zingibera*.
2. *Alpinia*.
3. *Costa*.
4. *Curculon*.
5. *Globus*.
6. *Hitchkinia*.
7. *Kempferia*.
8. *Asarum*.
9. *Cassianara*.
10. *Ganadza*.
11. *Deltaria*.
12. *Donae*.
13. *Dorado*.
14. *Dirada*.
15. *Phoeberia*.
16. *Hedycesium*.
17. *Pepperdium*.

Nearly all the species are tropical plants, and by far the greater number inhabit various parts of the East Indies; they are also found in Africa and America.

The plants belonging to this order possess great beauty, on account of the development of their floral envelopes and the rich colours of their bracts. They are also employed in the medical, and especially in the cosmetic, art as the true ginger. The Z. officinarum and common Ginger, has subsessile, linear-lanceolate, smooth leaves, elevated oblong spikes, acute bracts, and a 3-lobed lip. The rootstock of this plant is the ginger of commerce. It is imported into England from various quarters of the world, but more especially by the East and West Indies. This plant is now grown in almost all parts of the globe in tropical climates, but it seems to have been originally indigenous in the East Indies. The ginger plant may be propagated by seeds or by cuttings of the root. When the cuttings are planted out in spring, they is the mode generally pursued in its cultivation, in course of three or four months their rootstocks have a mild aromatic flavour; and it is in this state they are used for the preparation of what is called preserved ginger. At the end of the year or the beginning of the tenth month, they are considered fit for the market of commerce. The rootstocks are then prepared in two ways: either by scalping them in boiling water, and drying them with artificial heat; or by peeling, and drying them in sunshine, without immersing them in hot water. The former is the mode of producing *Thick ginger,* and is used for that of the white ginger of commerce. The chemical composition of the rootstock of ginger, according to Bucholz, is as follows:

Ginger is one of the most agreeable of the hot spices, and is consequently much used as a condiment. It also enters into the composition of many medicines, as it acts as a carminative.

2. *Zernobset,* the Broad-leaved Ginger, is a native of the East Indies, and has delicate stems; bifid and sickle-shaped leaves, a spike of small flowers, and a yellow scarlet lip. The rootstock of this plant is much used in the East for cuttlefish and cephalopods, but is not taken internally.

The genus *Alpinia* has an uncrowned anther, the inferior limb of the corolla with one lip, the epicalyx with three lobes, the seeds with three caryopses, and the rootstock is now in honour of Prosper Alpinus, an Italian physician and botanist, who lived in the sixteenth century. This physician to the Venetian consul at Cairo, and then stayed in Egypt made several excursions into the desert, and collected more information with regard to the natural history than had been done by any previous traveler. On his return from Egypt he published a work on the natural history of that country, and especially on the plants of other countries which he had collected there, through the courtesy of that part of the world. He was professor of botany at Padua, and died in 1608 at the age of 64.

This is one of the largest genera of Zingiberaceae plants, one of the species, *Alpinia officinarum,* puts a part of the seeds known by the name of Cardamom (Cardamomum). They are all splendid plants, and form a handsome addition to our hothouses. They require a rich soil, and plenty of room. *Rascroo,* a handsome species, is best cultivated as an aquatic.

*Hedychium* is a beautiful genus of plants. They have a graceful stem, and all the species are called Ginger-flower. The anther is naked, the tube of the corolla is long and slender, with both limbs triplicate, and the styles 3. In cultivation, the species, of which *H. angustifolius* is a one of the handsomest, they require a rich and large pots to make the plants flower well.

*Kempferia,* a genus named after Engelhard Kempter, the Japanese medicine and medicine man of the 2-lobed crest and tube of the corolla long and slender, with both limbs triplicate. The plants belong to this genus have a stem. There are several species, all of them native of the East Indies, and all are known by the name of *Gala* flowers. Some of these plants have a large a species of the genus, with a sharpish acid taste, and are used as condiments and medicines.

*Roconta,* a small genus of the order, was named in honor of the Rosco, the historian of the *Medici,* who published a monograph of the plants belonging to the order Zingiberaceae.

The genus *Globosum* contains species which produce spires of smoky-coloured berries, which are about the size of grapes, and are sometimes thrown out in great profusion by the East and West Indias. This plant is now grown in almost all parts of the globe in tropical climates, but it seems to have been originally indigenous in the East Indies. The ginger plant may be propagated by seeds or by cuttings of the root.
division Heliospides of that tribe. It was named by Linnaeus in honour of Dr. John Godfrey Zinn, professor of physics and botany at Göttingen, and author of a work entituled "Physiologia Plantarum Horti Academici et Agri Göttingensis," which was printed in 1749. He also wrote several treatises on various points of physiology. He was a pupil of Haller, and followed his master in the adoption of his system, in opposition to that of Linnaeus. He died in 1758.

This genus very closely resembles Rudbeckia, with which it was originally confounded by Zinn himself. It has a chaffy receptacle, the seed-down consists of two erect unequal awns, the calyx imbricated, somewhat ovate, the petals, however, the most remarkable part, is divided. All the species are natives of South and North America; they are annuals, and form handsome border-plants in gardens. They may be propagated by seeds, which should be sown on a slight hothot bed early in the spring, under glass, and they should be pricked out on another bed previously prepared to receive them, where they may remain till the summer is advanced, when they may be planted out in the borders.

ZINZENDORF, NICOLAUS LUDWIG, COUNT VON, the founder (reser) of the sect of the Moravian Brothers, or Hermits [Moraviens], was the son of Count Georg Ludwig von Zinzendorf, chamberlain and state-minister of Augustus II., elector of Saxony and king of Poland. His mother, who showed so early a mark of her father's early age. His mother made a second marriage with the Count von Natzheimer, a Prussian field-marshall; and young Zinzendorf was educated under the care of his maternal grandmother, the widow of Baron von Gebsheim, and regularly at the court of Gottingen, where the hymns and treatises on religious subjects, and corresponded in Latin with several distinguished divines and scholars. This lady lived on her estate in Lusatia, where she was frequently visited by pious men; the celebrated Jacob Spener is said to have conversed with her, and to have imparted to her the knowledge of the divine, which was considered the head of the Pietists, which produced in the mind of young Zinzendorf that religious tendency which made him notice what a marked character he had formed 50 years ago led him to reform his imagist faith. In 1710 Zinzendorf was sent to the Paedagogium at Halle, which was then directed by Francke, to whose particular care he was intrusted. In that school Zinzendorf remained six years, and as Pietism was the ruling principle there also, he abandoned himself entirely to religious pursuits, and founded a mystical order among his fellow-pupils, which he called Der Orden von Senk-korn, or the Order of the Grin of Mustard-seed, in allusion to the passage in St. Matthew (xi. 31, 32). His family was a prosperous one, having purchased the occupations of a young nobleman, whom they wished to bring up as a statesman, and not for the church, which had been deserted by the Protestant nobility of Germany since the bishops and rich prebendaries had been abolished by the Emperors. David according to the order of the Electress of Halle, sent him, named Christian David, a carpenter from Moravia, who had travelled much; he belonged to the obscure sect of the Moravian Brothers, who professed the doctrines of John Huss in some remote corners of Moravia. David, who was ordered to take the youth to be educated under the canonesses, under which they lived under the Austrian government, Zinzendorf invited him to settle on his estate, and to bring thither such of his friends as would prefer liberty of conscience in a foreign country to religious oppression at home. He and his flock soon attracted the attention of the summer of 1722, with three men, two women, and five children, to whom the count gave some land and a wooden house situated at the foot of the hutberg, or pasture-hill. "Such was the beginning of the celebrated colony of Herrnhut; forever renowned which signifies 'the lord's guard,' was given by Zinzendorf to the settlement in allusion to the double meaning of the word 'Hut,' which signifies 'guard,' as well as 'a place where flocks are guarded; that is, a fortified settlement." The settlers were so poor, that the countess presented them with some clothes and a milk cow, to prevent the children from starving; but they were industrious and good people, and soon got into better circumstances.

Zinzenzendorf conceived the idea of forming a sect, and he published the principles of the new creed in several pamphlets, which sometimes contradicted one another, but from which we may nevertheless see that he did not intend to separate from the Augustan Church. Herrnhut was destined to he the centre of that sect, and he invited other Moravian brothers, whose religious principles seemed to him to correspond best with his own, to settle in the new colony, to which he gave his solemn benediction. He supported the settlers with great liberality, and he and his flock soon attracted the attention of Germany and other Protestant countries. The mor
of his adversaries increased with that of his followers; he
was attacked publicly and privately; but he also received
proofs of respect and esteem from the highest quarters:
the emperor Charles VI. invited him to his court at
Vienna, but Zinzendorf declined this honour as well as
many others, and remained faithful to his principles.
Heathen, Zinzendorf went to Copenhagen in 1731, for
the purpose of inquiring into the state of the Danish missions
in Greenland, and the East and West Indies; and he despatched
several of his disciples as missionaries to those countries.
This is the origin of the system of the Moravian missions,
which are now scattered over the world. The king of
Denmark, Christian VI., rewarded his zeal with the Knight
Cross of the Order of Dannebrog, which Zinzendorf
accepted; but he sent it back five years afterwards. In
1734 he returned to Stralsund, for the purpose of being
ordained a minister of the Lutheran church. As
his enemies were numerous, he adopted the name of
Ludwig von Freideck, and engaged himself as tutor in the
house of a merchant named Richter. After having been ex-
amined by the members of the consistory at Stralsund, he
received ordination and preached in the chief church of that
town. It is said that he became a tutor because he had
devoted all his property to the establishment of his colony
of Herrnhut, and wanted a livelihood; but this is scarcely
credible, for he had lost his property, he devoted his
herents would have supported him; or his brother-in-law,
the count of Reuss-Ebersdorf, who was his sincere friend,
would have supplied him with the necessary means.
Besides, Zinzendorf continued to travel about the world;
and also on more frequent occasions in Hesse-Cassel,
where he often went to Stralsund for the purpose of
the Moravian missions. This was because he spent large sums at once, he was never obliged
to give up his plans for want of funds. In 1735 he intended
to go to Sweden, but, on his arrival at Malmeoe, he
was ordered to leave the kingdom immediately. Upon this he
sent his letters to the king of Sweden, Frederick
given in a pamphlet, of which he sent copies to the principal
courts of Europe. This made him new enemies, and in
1736 he was banished from Saxony on the charge of having
introduced novelties and preached dangerous prin-
ciples, which endangered the authority of a Lutheran
prince and threatened to weaken the authority of the government and to bring
into contempt the services of religion as practised by the
Protestant church. Zinzendorf took refuge with his
brother-in-law, the count of Reuss-Ebersdorf, who was
sovereign minister of the empire; and it was only in 1747
that he was allowed to return into Saxony. In the same
year, 1736, he went to Holland, at the request of the
princess-dowager of Orange, and founded the colony of S:"Heer-
endyk (the lord's dyke), which was afterwards transferred
in 1737 to South Carolina, with the assistance of the Livonian
and Esthonian languages, and established several Moravian
colonies there. On his return he was invited to Berlin by
the king of Prussia, Frederick the Great, who had already
undertaken the education of Zinzendorf, whom he believed
to be a vulgar fanatic; but so soon was the count intro-
duced to the king, and spoke to him with that gentle
and noble persuasion which had always distinguished him,
than the king changed his opinion. Their conversation lasted
three days, and the king was pleased with him that he
promised to acknowledge him as bishop of the Moravians,
if the count would be ordained. Zinzendorf having agreed
to the proposal, the Reverend Jablonski, who held the
office of the first of court preachers, ordained him
bishop (May, 1737). The ordination of a bishop by
who was not a bishop, was hardly in accordance with the
canon law; but as Luther had ordained a bishop (Ams-
dorf), although he himself was no bishop, the practice
seemed to be justified; and the remonstrations finally con-
tributed to raise Zinzendorf in the opinion of the world,
although, strange enough, the king of Prussia would not
allow him to preach in public.
About this time Zinzendorf was informed that he might
return to Saxony if he would sign a paper declaring
himself a churchman and that he would not be deterred
against him by slanderers, but he nobly refused to do so,
and continued to live in exile. In the same year (1737)
he went to London, and held private meetings in his house,
where were attended by a great number of both
pious and curious persons, and led to the establishment of
a Moravian congregation. Wesley received him with
great kindness and esteem: and it is said that each of
them tried to convert the other, but of course without
success. They were often engaged in discussions on
religious subjects, and they argued particularly the question,
whether men could attain perfection in this world, which
Wesley affirmed, but Zinzendorf denied. From London
Zinzendorf went to Spain, where he was received with
much favor, but he declined the post of governor of
the West Indies, and on his arrival there found that the
Moravian missionaries who had been sent thither a year
before had been thrown into prison, and the
chaplains shut up by order of the local government. He
succeeded in obtaining their liberty, and defended his
their cause with so much eloquence that the governor
remained not to obstruct the religious services of the
bewitch. He now returned to Germany, made a be
Switzerland, where Vernet and other French writers
considered him as the most learned and profound
ist, but avoided any intimacy with him; and in 1738
set out for his great tour to the British colonies in
America. He was accompanied by his daughter, who
then was only sixteen. No sooner had he arrived in
Pennsylvania than he was assaulted by accusations of the
regulating and revolting description, which he supported
for his usual calmness and forbearance. At Germanias he
performed divine service regularly every Sunday, and
made himself so popular that the inhabitants, who were
indulging in public revels and debauches, went to the
office with visible satisfaction, and being afterwards
obliged to continue his travels, wrote to Hermut, to
caused one of the preachers there to come over to America
at his own expense, and to take his place as minister.
In Germany, he had often received the visit of
his people, with respect, and was supported at his own expense, for the use of the Moravian con-
gregation, which had hitherto assembled in a barn. At Phila-
phia Zinzendorf delivered a Latin speech in presence of
numerous auditory, to whom he declared the necessity
of giving up the right of arbitrary manner in all the
rural policy of all the country, and Zinzendorf was accused of having consulted
them to such proceedings. However, so far as he
ever had ever had the slightest idea of propagating his
opinions by other means than those of reasonable means,
he invited them to write a letter to him in order to justify
himself. On arriving at Riga he received an order from
the empress Elizabeth to leave the empire immediately
and he was put under a military escort, which accompanied
him on his return as far as the Prussian frontier.
He went on, however, without the permission of the
inhabitants. A few years after this he was allowed to
return to Saxony (1747). During his exile the brethren
increased in number and wealth, and their goods
industry and trade had multiplied many times, so that the
people of rank, so that the government gradually treated
them with less severity. Zinzendorf's numerous
powerful friends also pleaded in his favour, and the
government was finally persuaded of the relative
honesty by an offer of the brethren to the archbishop
Bartholomaeus Thumstein, to shut the castle
door of use, as the castle was half in ruins and the
barren, and for which the brethren offered to give
hundred and fifty thousand thalers (25,000$)
be might be allowed to establish there a settlement.
The Saxon government assented, full liberty of refuge
was granted to the brethren, and Zinzendorf returned
to Herrnhut. In 1749 he went to England, and through
protection of Archbishop Potter, General Oglethorpe,
and several other men of influence whose services
secured an act of parliament for the establishment of
Moravian colonies and missions throughout the British possessions in
North America. He now set out for America to carry
his undertaking into execution, and after an absence of
years he returned to Herrnhut. His last great tour was in
1757, when he visited his friend Von Wavettke at Montreux
in the canton of Bern in Switzerland, where he proved
ZIRCONIA. [Zirconium.]

ZIRCONIUM, a peculiar metal obtained from the earth or metallic oxide zirconia. It is procured by heating the double fluoride of zirconium and zirconium, or zirconium with potassium in a glass or iron tube. When the cooled metal is treated with water, a black powder very much like charcoal remains, and this is zirconium, containing however some hydrite of zirconia, from which it is freed by hydrochloric acid; being afterwards washed with hydrochloric of ammonia and alcohol, it remains nearly pure.

The properties of zirconium are,—that under the burner it assumes the lustre of iron, and is compressed into scales resembling graphene. When heated in the air, even in a yellow redness, it takes fire, and by combination with carbon is converted into oxide of zirconium, or zirconia. Alkalies or acids, except the hydrofluoric acid, produce little effect upon zirconium, but this dissolves it with the evolution of hydrogen gas.

Zircon or zirconia, constituting the earth zirconia, exist in the state of silicate in the zircon, and also as a titaniate in the masonite. [Titanium.] Its properties are,—that it resembles alumina in appearance; is inodorous, insoluble, and insoluble in water. It is sufficiently hard to scratch glass. When heated by the blow-pipe, it phosphoresces vividly.

It appears to be composed of—

One Equivalent of Oxygen . . . 8
One Equivalent of Zirconium . . 22
Equivalent . . . . 30

Zirconia forms salts with acids, which possess the following characters:—They have an astringent taste; they are precipitated by the caustic alkalies and acids, and an acid solution of zirconia is boiled with sulphate of potash, a subalsalt of zirconia is formed, and being insoluble in water. Infusion of galls produces a yellow precipitate, and phosphates of soda a white one; carbonate of zirconia, when recently precipitated, is soluble in bi-carbonate of soda and of potash.

ZIRKONIT. [Kirkniitz.]

ZISKA, or more correctly ZIKA, OF TROCNOW, JOHN, the celebrated leader of the Hussites, was born under a black-tree in the open fields, near the town of Trocnow, in the circle of Budweis, in Bohemia, about 1360, or, as some say, about 1380. His father, the lord of Trocnow, was a Bohemian noble of more credit than wealth. John Ziska lost one eye at an early age, and hence it was said that he was called 'Ziska,' which 1505 signifies in the Bohemian language. But this fiction; Ziska was the name of his family, and it does not signify one eye either in Bohemian or in Polish.* At the age of twelve John Ziska was received among the pages of Wenceslaus, king of Bohemia and emperor. In 1389 he became distinguished among his fellow-pages by his gloomy temper and his love of solitude. Disgusted with the trifling and capricious character of Wenceslaus, Ziska left the court, and sought his fortune abroad. For some time he served as a volunteer in the army, and distinguished himself against the French. He afterwards went to Poland, and commanded a body of the Bohemian and Moravian auxiliaries of King Wladislaw II., Jagiello, in his war against the Knights of the Teutonic Order. The dreadful battle of Tannenberg (10th of July, 1410), in which the grand-master Ulrich von Jungingen was slain, with 40,000 knights and soldiers, was decided in favour of the Poles by those auxiliaries, and John Ziska distinguished himself so much that King Wladislaw rewarded him with a chain of honour and other rich presents. The hero of that battle by that battle, Ziska fought against the Turks in Hungary, and having again entered the English army, won fresh laurels at the battle of Azincourt (1415). After this he returned to Bohemia, and accepted a place as chamberlain at the court of Wenceslaus (1419), against his own inclination, and for reasons unknown.

Ziska was an adherent of the doctrines of John Huss, and the fate of this reformer and his friend Jerome of Prague, who were burnt at Constance, in 1415, was considered by him as a signal to his country. His hatred of the Roman Catholic clergy was increased when his favourite sister was seduced by a monk. He became conspicuous among those Bohemian nobles who urged King Wenceslaus to revenge the insult, and to pro-

* There are still Ziska’s living in Bohemian.
test the followers of Huss against the decisions of the synod of Constance. The king, seeing him one day from the window of his palace walking in a thoughtful mood, asked him what he was meditating about. 'Upon the bloody affront,' answered Zizka, 'which the Bohemians have suffered at Constance.' 'It is true,' replied the king, 'and I know it too; but if you leave it as it is neither in your interest nor in your power to revenge it. If you can do so, I give you my royal permission.' It is said that this circumstance first inspired Zizka with the resolution of defending with his sword the religious liberties of his country. But Wenceslaus was a man of coldness and tact, and he was alarmed at his own resolve, and his perplexity was augmented when he was informed that the Bohemian nobles had resolved to take up arms in defence of the dignity of his own person. Their leader was Nicholas of Hussa, Jerke, and Zizka was not venturing to appear before the king though they acted with his permission. Zizka however persuaded them to follow him, and having been received by the king, spoke to this effect—'Sir, behold a body of your majesty's loyal subjects. We have brought our arms, as you commanded. Show us your enemies, and you shall acknowledge that our weapons can be in no hands more useful to you than in those which hold them. Take your arms, replied the king, after a moment's hesitation, and go to conduct these people; your presence recommended him to the confidence of his party. But the king's energy was not real; he did not protect the followers of Huss; and the Roman Catholic party became still more insolent. On July 18, 1419, a new battle was fought at Mount Valtice outside of the walls of the city of Breslau. It was the battle of Valtice where Zizka was again victorious, and the Hussites were again victorious. Rut the emperor, after the battle, inscribed the property of the town of Zizka as a crown of honor to his majesty. They retreated towards Moravia, and were sore pressed by Zizka that they crossed the frozen Isga in their bodies, and, as the ice broke, about 2000 of them were drowned. In the same year Zizka obtained a decree from the Emperor to be elector of Saxony and Brandenburg. The Saxons however were excellent soldiers, and on their first contact with Hussites were so well received that they retired in confusion, and then stood still facing their enemy with the assurance of an overwhelming victory. They fell into a trap and they believed that nobody could resist them. The first Zizka approached on his cart and said:—Well, brethren, I thank you for all your past services: if you now done your utmost, let us retire.' This noble chide roused their fanatical courage and in a second attack the Saxons were routed and left 6000 dead on the field. Siegmund now saw that he could never conquer Bohemia, and he proposed an arrangement, to which he was the more inclined after some of the Bohemian states had been taken and Wenceslaus was crowned. He removed to Prague and sent Prince Korybut to Pardubitz as his vicere. But Korybut, being only supported by part of the Hussites, could not maintain himself, and was compelled to retire to Lithuania. On the other hand there was great joy for Zizka, made by the victory, although his own authority was not shaken, the animosity between the minor sects of the Hussites was too great to allow the prospect of a lasting political union among them. Siegmund proclaimed to grant full religious liberty to the Hussites, and to appoint Zizka governor of Bohemia and her dependents with great power and privileges. But Zizka did not like to complete the treaty, which was ready to be concluded after an interview had taken place between himself and the emperor. He found a convenient pretext to break the terms of the treaty in his demand for equality and with the confidence of a sovereign his. Zizka gained the county of Duchcov during the negotiations. Zizka laid siege to the castle of Prague, which he took in 1421, and there found four cannons, the first which he had in his army. He soon increased his artillery, and he procured a great quantity of small fire-arms, which had hitherto been very little used in warfare. He gave fire-arms to a considerable part of his army, and from this time they gradually became general. The Hussites were now in a new position, and they were very efficient in cavalry, and, in order to protect their infantry against the attacks of cavalry, he invented, or rather introduced again, an ancient kind of barricades, made of baggage-carts, which is known by the German name von Wagen, or wagon defence. These were not the only weapons of Zizka, whose name will ever be conspicuous, not only as a general, but also as an engineer. In the year 1421 Zizka lost his other eye by an arrow during siege of the castle of Raby; but he nevertheless continued to hear his food in the town of Orlich he was encamped in cart, and he arranged the order of battle according to the description of the ground made by his officers. In this difficult business he was greatly supported by his canvas and his complete geography of Bohemia. Meanwhile Siegmund had levied a new army in Germany, the flower of which was a body of Polish Hungarian horse, who were considered the best in Europe, and were commanded by an Italian officer of great experience. The Hussites advanced into Moravia in January, 1422. Historians speak of the onset of Zizka as a shock beyond all credibility, and it appears that they have not exaggerated it. The imperial infantry made a stand at all, and the horse took to flight after a brief battle. When the battle was over, Zizka and his followers retired to Prague, where he was appointed the governor of Bohemia. Zizka became a Roman Catholic, and was received with great joy by the Bohemians. Zizka was succeeded by Wenceslaus, who was elected king by the Bohemians.
asked who was buried there, and being informed that it was Zizka, he cried out in Latin, 'Phui, phui, mala bestia, quae mortua etiam post centum annos terret vivos!' (Lo, the wicked beast, one hundred years dead, and still frightens the living!) The emperor was actually so frightened that he left the church without staying, and would not stay the night at Czsalu, but proceeded on his journey. There is a common but idle tale that Zizka on his deathbed ordered his skin to be tanned, and put over a drum in order to frighten his enemies after his death; and it is also said that the insides used that drum in many a battle; all this is fabulous.

After Zizka's death the negotiations with the emperor were broken off; the Taborites chose Procop the Holy for their leader; the Orates, Krossins; and the Orphanites, Peter of Vratislav. The war continued for nearly two years more, till it was finished by the treaty of Prague, in 1433, in consequence of which Siegmund was acknowledged king of Bohemia.

ZITTAU, a town of Upper Saxony, is the kingdom of Saxony, in 50° 52' N. lat. and 14° 45' E. long., is pleasantly situated in a small valley on the river Mandau, not far from its junction with the Neisse. It is surrounded by forest in most parts and was nearly destroyed in 1579 by the Austrians, who besieged it, of which occasion 600 houses were burnt, it was rebuilt in a much better manner, and is reckoned, after Dresden and Leipzig, one of the handsomest towns in Saxony. It has 1400 houses, 1 presbytery, and 69 Protestant Protistus. It is the centre of the linen manufacture, and of the linen and damask trade of Saxony, and, on account of its great traffic, has been called Little Leipzig. There are manufactories of linens, woollens, cotton yarn, leather, dyes, for the establishment of gardens, &c. The magistrates have extensive privileges, with jurisdiction over 45,000 inhabitants, for thirty-five mostly large manufacturing villages, and large estates, belonging to the town. The public revenue is therefore considerable, and all the institutions well provided for. There are five churches, a gymnasium, an admirable town freeperson, and a seminary for schoolmasters, a school of industry and Sunday-school, numerous well-founded charitable institutions, an orphan asylum, a savings-bank, the rich hospital, &c. It is famous as a dry goods and theatre. Some of the churches are handsome buildings, especially the new church of St. John. The city library, the largest in Upper Lusatia, contains 13,000 volumes; a cabinet of natural history; and many curiosities, among which are a letter sent to the emperor by the 1th of June, 1609, by the emperor Rudolph II. to the Bohemian Protestants, securing to them the free exercise of their religion. The necessaries of these letters patent by the emperor Mathias, in 1499, was one of the first and principal causes of the Thirty Years War. There is still a Bohemian Protestant community of 1000 persons in the suburb, who have a church in the town. The town is surrounded by fine public promenades, planted with trees, from which there are extensive views towards Bohemia.

The export trade is very considerable: that of linens and damasks is to the amount of 500,000 rix dollars annually. There is likewise a profitable transit-trade to Bohemia. Near Zittau is the Lausche, a mountain belonging half to Bohemia and half to Saxony, from which there is a very fine and extensive prospect of Upper Lusatia, and part of Meissen, Bohemia, and Silesia.

(Z.) Zizka, the Common Jujube, has ovate, retuse, toothed, smooth leaves; prickles absent or twin; and an ovate oblong drupe. This plant is a native of Syria, from whence it has been introduced into Europe. It is now cultivated in many parts of the south of Europe, where its fruit is known as the Jujube. It has yellow-greenish flowers, two or three of which grow together. The fruit is of a blood-red or saffron colour, and has a sweet granular pulp. In Italy and Spain it is eaten as a dessert when fresh, and in the winter season when dried. It is used in the quantities in the markets of Constantinople. The Jujube is commonly planted by the Turks of Constantinople before their coffee-houses for the sake of its shade. Dr. Hamel recommends the general introduction of the tree on account of the seeds for medicinal use. The fruit is somewhat acid; the flesh is firm, and, when dried, forms an agreeable sweetmeat. A syrup made with it is recommended in coughs and catarrh, and lozenges of it are used for the same purpose. The fruit does not ripen in Great Britain nor in Paris, but it does in the south of France. This plant was introduced into England in 1640. Although it attains a height of 20 or 30 feet in its native countries, it does not grow to anything like that height here. It produces a soil that is dry to one that is moist. It is easily propagated by cuttings of the roots, or by suckers, which it throws up in great abundance. The seeds obtained from plants grown in Italy will germinate freely when sown in this country.

(Z.) Zizulaeus. Chinese Jujube, has ovate oblong, acute, serrated leaves, glabrous, except beneath, along the nerves; pubescent branches; reflexed petals; twin straight prickles; and ovate drupe. This plant is a native of China, and has greenish white flowers. It has a brownish, small, rough, and calcaneous calyx. The fruit is sold in the markets of Canton during the autumn.

(Z.) Z. spina-Christi. Christ's Thorn, has ovate, toothed, smooth leaves, pubescent beneath; prickles twin, one straight, the other incurved; the peduncles eorymbous; the flower ovoid-globular; the fruit ovoid, 2-inch long, is covered with thorns, and is a native of the North of Africa, of Palestine, E. of Asia, and Egypt. The flowers are yellowish green. The fruit is oblong, about the size of a scone, and much eaten in Egypt and Arabia. This plant has plant branches, and
is round and surrounded by numerous long filiform tenta-
cula. The *Alcyonides Scoticus* was found in four fathoms
of water off Loch Ryan.

4. *Actinia*, Linnæus, now restricted to such species as
have simple tubular retractile tentacula, and adhere by a
broad base. Ehrenberg has separated such *Actinae* as
have a glandular epidermis, under the name of *Oribrina*.
From the glands protrude long filaments, the uses of
which are unknown. The tentacula of all the species are
(contrary to the supposed of Ehrenberg) perforate at
their extremities. (*Actinia.*) The subgenus *Adamaea*
has been constituted, by Professor E. Forbes, for the
reception of the curious parasitical *Actinia maculata*, which
envelopes the mouths of dead shells, generally selecting
such as have been previously invested by the *Aleyandonium*
echinatum. As such shells are frequently inhabited at
the same time by the Hermit Crab, not a few naturalists
have mistaken the coincidence for some necessary and
mysterious friendship of the zoophyte for the crustacean.

5. *Anthea*, Johnston, includes such *Actiniae* as have
not the power of retracting their tentacula. Several of
the species grow to a large size.

p. 222, fig. 33.

in which the entire disk is divided at the margin into more
or less rounded lobes, which bear short simple tentacula.

Example, *A. dactylus*, Phil. Trans., *viii.* tab. 18, fig. 8.

7. *Capnea*, Forbes, of which one species only is known.
The disk is round with several circles of exceedingly short
or simple tubercular retractile tentacula, and the body is in part
invested with a peculiar epidermis, which is divided at the
margin into eight lobes.

Example, *C. sanguinea*. *Annals of Natural History,*
vol. vii., pl. 1, fig. 1. Irish Sea.

C. Sea-Anemones having more or less pinnate tenta-
cula.

8. *Actinaria*, Quoy and Gaimard. Such as have the
entire disk covered by very small villose ramified tenta-
cula.

Example, *A. villata*, Quoy and Gaimard. *Voy. Astro-
labe*, Zooph., p. 49, figs. 1, 2. Tonga Islands.

9. *Actinodendron*, Quoy and Gaimard. Species having
very long arborescent tentacula disposed in one or two
series on the oral disk.

1, 2. This animal is more than a foot in height, and
secretes a stinging mucus.

11. *Thalassoctis*, Leuckart. One species only known,
the *T. aster*, an inhabitant of the Red Sea, figured in the
plates to Ruppell's *Voyage.* Its tentacula are numerous,
short, and pinnate. It is probably identical with the
*Epilasma* of Ehrenberg.

11. *Heteractis*, Ehrenberg. The tentacula are of
two sorts, some simple and others pinnate.

12. *Megalocita*, Ehrenberg, founded on an animal from
the same locality with the last, and characterized by
having all the tentacula arborescent, but the internal ones
are the larger and more pinnate, and have their ex-
remities hollowed into a sort of socket.

Example, *Megalocita Hemprichii.*

Family III. Zoanthide.

The genera of this family are few, and the animals
included in them have by some been mistaken for
Alcyonias.
The following revision of M. de Blainville’s table of
Stony Zoophytes exhibits the number and relations of
genera of the Madreporidae.

**For figures and descriptions of the more remarkable of these genera, see Astrea, Madrephylax, and Madrepaura.**

Fossil Zoantharia. Until lately it was supposed that no traces of pre-existing species of the soft Zoophytes existed; and indeed the structure of the Actinidea rendered it improbable that any such should be found. Professor Bailey however has described, in the "Boston Journal of Natural History" (1843), some microscopic fossils, which he considers as analogous to the spicule which are found in the epidermis of certain American species of Actinidea. Fossils of the family *Milleporidae* are very abundant, and among the most important of organic remains, considered in a geological point of view. In Mr. Morris’s Catalogue of British Fossils (1843), nearly 150 species are enumerated as described remains in British strata. Of these by far the greater part are derived from the oldest rocks, and are among the strongest evidences we have of a universal warm climate during the earlier epochs of the world’s history.

ZOBEI, BENJAMIN, the inventor of marmotinto, was born in 1762, at Memmingen in Bavaria. He received his education at the government school of that city, and acquired the rudiments of drawing from one of the monks belonging to the convent of Otterbeurn. In 1781 he went to Amsterdam, where he resided for two years, occupying himself chiefly in portrait-painting. In 1783 he came to London, where he formed acquaintance with Morland and Schweickhardt, the latter of whom was employed at Windsor Castle by George III. ’s “table-decker.” It was then the custom to ornament the royal dinner-table by having a silver plateau extending along the centre, on which were set various costly dishes, or milled board, in the design of fruits, flowers, arabesque-work, &c. For this an artist of considerable talent and of great freedom of hand was required. On the retirement of Schweickhardt, Zobel was appointed; and he continued to fill the office for a considerable period. Ornamenting the royal table in the manner just described was a daily occupation, the sand not being cemented by any substance. From this occupation arose the idea in the mind of Zobel of producing a finished and permanent picture, by the use of some substance by which the sands might be fixed. After various experiments, a composition (in which gum-arabic and spirits of wine formed the chief ingredients) was found to answer the best. The subject of the picture having been designed either on a pannel or milled board, a film of the glutinous substance was spread over it; the different coloured sands were then used in a similar manner as that employed in deck ing the royal table, viz. by stirring them from a piece of card held at various elevations, according to the strength or softness of the film. Thus in this way a finished picture, not subject to decay, and perfectly permanent in all its parts, and this was called by the inventor, Marmotinto. Some of the best specimens of this peculiar art were formerly in the possession of the late Duke of York, but were sold, at his death, at Ouida. Some are still among the collections of paintings belonging to the Duke of Northumberland and Sir Willoughby Gordon.

Painting on gold and silver grounds in transparent colours for the representation of cabinets of humming-birds, &c. was also practised with eminent success by Zobel. He died in 1831.

ZODIAC (in Greek Ἐτηκος, zōdaios, ’the Zodiac circle’) is a name given to a zone of the visible heavens, extending in breadth to certain equators on the sides of a great circle of the celestial sphere, in the plane of the earth’s orbit produced. This circle, with which the apparent annual path of the sun coincides, is called the ecliptic; at present it makes with the plane of the earth’s equator an angle equal to about 23° 27′ 33″, and is divided into twelve equal parts, called signs, which receive their denominations from those of the figures intended to designate the constellations or groups of stars about it. Most of the figures being those of animals, the name of zodiac (from ἔτηκος, zōdaios, the diminutive of λέγω, zων, ‘an animal’) has, in consequence, been applied to the zone.

The planes of the orbits of all the planets, when produced to the celestial sphere, are supposed to be comprehended within the breadth of the zodiac, and that breadth is determined by two small circles parallel to the plane of the ecliptic. Before the discovery of the planets Ceres, Pallas, Juno, and Vesta, the greatest inclination of the orbit of a planet to the ecliptic was scarcely exceeded 3 degrees, and therefore the breadth of the zodiacal zone was imagined to be about 16 degrees, or 8 degrees on each side northward and southward of the ecliptic. The orbit of Pallas (that which deviates most from the ecliptic) is inclined about 35°, and it now becomes evident that the breadth of the zodiacal zone is about 70 degrees.

The line in which the plane of the ecliptic intersects the plane of the terrestrial equator, being produced indefinitely, cuts the celestial sphere in two points diametrically opposite to each other; and one of these meeting the heavens, in the age of the earliest Greek astronomy, near certain stars forming a constellation to which the figure of a ram (Aries) was assigned, is generally called the first point of Aries. From this point are reckoned, on the ecliptic, the longitudes of celestial bodies; and on the equator, their
right ascensions. The twelve equal parts or signs into which the ecliptic is divided are distinguished by the names of the constellations which, in the age above alluded to, fell within their respective extents in longitude; and the names both of the signs and constellations are as follow:—Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, and Pisces.

The distribution of all the visible stars into groups or constellations was the first step in laying the foundation of astronomical science. It must have taken place in the earliest ages of the world; and there is the highest degree of probability that the zodiacs of all nations have been derived from a common source, though in passing from one people to another it may be easily conceived that the figures would suffer changes from the vanity or caprice of individuals. Among the antients, the place of the sun in the zodiac served to regulate the seasons of the year; the representations of the figures associated with the groups of stars were almost constant ornaments of the religious edifices; and superstition assigned to the regions of space influences on the lives and characters of men depending upon the qualities of the animals or objects which distinguished the constellations in the corresponding parts of the celestial sphere.

The loss of the writings of the antient Babylonians, and the entire destruction of their edifices, have deprived the world of every monument by which light might be thrown on the state of astronomy among a people whose priests, according to Strabo, were mostly engaged in the study of the science. In fact our information respecting it consists chiefly of the notices given by Ptolemy concerning a few of their observations, and from the evidence of Diodorus Siculus states (Biblioth. Histor., ii. 30) that the Babylonians had twelve chief deities, to each of whom they assigned a month, and one of the so-called twelve animals by which he means the twelve parts of the zodiac; and from this it may be inferred that they divided the zodiac into twelve signs. Sextus Empiricus (Adversus Mathematicos, lib. 1) makes a like statement, and shows how, by means of a zodiaconic representation of the signs, a few fragments only of stones, having on them figures which may or may not have been intended as representations of those which distinguish the constellations of the zodiac, have been dug up near Bagdad; and the most remarkable of these is one having on its face a solar disk surrounded by a serpent: the figure may have designated Ophiuchus and it is possible that it may have been part of a Chaldean planisphere. The division of the zodiac into twelve signs may have been originally made for the convenience of distinguishing the portions which the sun passes through in the several months; and a division into twenty-four parts is alluded to by Geminus (Eranos in Epigr. 97) which was probably made to denote the space described by the moon by her proper motion. The latter division was used by the Egyptians, the Greeks, and by the civilized nations of Asia; and the latter is found among the Persians, Arabs, Hindoos, and Chinese: the twelve parts are called the stations or abodes of the sun because this luminous sphere is in some one of them each day.

During the invasion of Egypt by the French, in 1798, General Desaix discovered some remarkable sculptures on the ceiling of an apartment in the great temple at Denderah (the antient Tentyrna), and MM. Jollans and Desvilliers almost immediately perceived among them figures nearly similar to those which are traced on celestial globes at the present time. The whole of the astronomical figures are within the circumference of a circle about ten feet in diameter; and the apartment in which they were found is in the upper part of the building: adjoining to an apartment of equal size, which is open to the sky, is an apartment of equal size, which is open to the sky by steps in the interior.
ZOD

apparently of an astronomical character, are found in several other apartments within the same temple; and in the ceiling of its portico are figures resembling constellations, among which are those of the zodiac disposed in two inner ones near each extremity of the portico, and parallel to the longitudinal axis of the temple.

The zodiacal figures in the apartment first mentioned are disposed nearly within the breadth of an annulus formed by two circles, whose common centre is at some distance, one near the top of the portico, and the second figure which is conceived to represent Cancer is however within the space inclosed by the interior circumference of the annulus, and nearly opposite the interval between Jeминi and Leo; that interval being occupied by a human figure which is a birth hieroglyphic. The figure of Cancer is also surrounded by a hieroglyphic symbol, which, according to Visconti, seems to express a proper name.

Except the zodiacal figures, scarcely any in the ceiling resemble those which are now assigned to the constellations; and a great effort of the imagination is required to discover in what manner they may be considered as emblems of the latter. From the zodiacal figures only it has been possible to determine the dates of seven stars which form the projection employed in the execution of the work, and the epoch to which the aspect of the heavens represented by it is to be referred.

The first discoverers of this ancient monument immediately saw in the hour or declination circles, if drawn upon it, would be represented by straight lines diverging from the centre, the latter is consequently the pole of the equator; but we are indebted to M. Biot (Recherches sur l'Astronomie Egyptienne) for the very probable idea that each hour circle represents the development of the whole surface of the celestial sphere, the adi of the circle being equal to half the circumferences of the hour-circles, so that the exterior circle represents the whole of the constellation, is supposed to be placed on the radii corresponding to the circumferences of the hour-circles passing through the groups of stars to which the figures belong, and at distances from the centre of the planisphere equal to the radii of the constellations. The figures of the two poles are supposed to be placed on the radii of the two poles of the equator. The distortion produced by such a development of a spherical surface is evidently very great near the margin; but a spectator who duly instructed, on comparing the figures near the centre with the circles of the heavens, the figures of the figures from the north pole in the north pole in the centre, it is not considered to refer; and the apartment without a roof, adjoining that which contained the planisphere, is supposed to have been intended for the computation of the position of the constellations by hour.

Our knowledge of the species of projection or development just mentioned is, that in the direction of a line passing through the centre, or pole, the distance between two points corresponding to two which are diametrically opposite is that which the pole of the world must have occupied about the year 716 a.c.; and he thence concludes that the planisphere presents the state of the heavens at the latter epoch." M. Biot afterwards calculated for that epoch the positions of the principal stars, and determined their situations on a plane by the rules of the projection supposed, as above mentioned, to have been used in constructing the Egyptian monument; on comparing the map so formed with an exact copy of the planisphere, he found the stars to fall upon or near the figures to which they were presumed to belong. Thus the stars of Ursae Minor fall near the centre, precisely on the figure of an animal representing the head of a dog with a crown; those of Orion and those of Sirion on the figure of a man, apparently intended for Horus, the son of Osiris, to whom, according to Plutarch (De Iside et Osiride), Orion was consecrated.

Several indications of the intentional displacement of the figures designating the constellations. In some cases, apparently when a constellation could not be conveniently introduced in its proper place for want of room, it has been transferred to the margin in the direction of a line drawn from the centre through the true place of the constellation. In other cases a constellation appears to be removed and a hieroglyphic figure substituted for it. Thus a line drawn from the centre of the planisphere, through Taurus, leads, near the magus, to a star which probably belongs to another constella-

tion; and near it is another group, which may represent the Hyades. Again, between Ariès and Piscis, and a little above them, is an animal in a sitting posture, which is supposed to coincide with the computed position of Mars in Cassiopeia; and near the margin of the planisphere, in a line drawn through the centre and this animal, there is a human figure seated in a chair, as Cassiopeia is always represented. In a few cases some emblem of a constellation has been supposed to be replaced by a hieroglyphic figure. One of the most interesting of the constellations is a figure with a winged globe is in the direction of a line drawn from the centre through the front of Ariès in the zodiacal ring. A great figure, which is supposed to represent a monkey rising near the centre of the zodiacal planisphere in a place corresponding to a part of the heavens very near Ursæ Major, but where there are no remarkable stars; and M. Biot conjectures that the animal may be an emblem of that constellation: he conceives that it may have been intended to represent a bull bearded which is represented by a hippopotamus, and to whom Ursæ Major is assigned. That the antient Egyptians had a constellation which was designated by this name is stated by Plutarch and by Diodorus Siculius (l. 27); the latter has given translations of two inscriptions in hieroglyphics which appear to have existed in his time; and in one of these Osiris is made to say that he had been to the uninhabited parts of India, to the regions of the Bear, and to the sources of the Danube.

In the direction of a line drawn from the centre of the planisphere, towards the north, and passing through the figure of Canes, is the representation of a cow having a great star between its horns; and near it, in the direction of a line coinciding with the longitudinal axis of the temple, is a tall lotus-stem surmounted by a hawk, the symbol of deity. On this stem the place of Sirius, computed for the epoch of the planisphere, is found to fall; and the cow probably represents Isis, to whom the star Sirius was consecrated. The solstitial colure being due north and south, it is probable that the planisphere was intended to show the aspect of the heavens at the time of the vernal equinox, when the colures pass through the four cardinal points of the horizon; and it seems to be intended to show the cow being in the plane of the solstitial colure is an indication that at midsummer, at the epoch of the planisphere, Sirius rose with the stars of Canes. The line representing the direction of the equinoctial colures passes, on the south side of the figure, a little way from which is a small figure (supposed to be Harpocrates) issuing from a lotus-flower, and having above his head a star with a hieroglyphical inscription. According to Plutarch (De Iside) the Egyptians represented the rising sun by a child issuing from a lotus; and the serpent with the symbols indicate the rising of the sun in the east point of the horizon on the day of the vernal equinox.

The heads of all the figures, with scarcely an exception, face towards the centre of the figure, and the figures in the southern half of the zodiac are arranged so that to a spectator standing in the centre of the room with his face to the south, and looking upwards, they must have
apparition as if moving from east to west; that is in the direction of the apparent diurnal motion of the heavens.

The longer axis of the temple is inclined to the meridian in an angle of about 17 degrees, and the walls are directed so that the points at which the remarkable stars Sirius and Antares must have seemed to rise coincided with the directions of the north and south ends of the building.

A temple near Esne (Latopolis), in the portico of which is a representation of the zodiacal signs, is disposed so that the longitudinal walls tend to the points at which Antares and Sirius rise, though no great stress is laid upon this circumstance, there is some probability that the dispositions may have been intentional, since no reason can be assigned why, otherwise, the temple should not, like the pyramids, have had their walls directed to the cardinal points.

The temple at Denderah, near to the temple of Isis, was 365 cubits in circumference, and to each cubit was assigned one of the 365 days of the year, with the rising and settings of the stars for each day marked on the several divisions.

The ceiling of the portico belonging to the temple at Denderah is nearly covered with sculptured figures, many of which resemble those in the circular planisphere, and the twelve signs of the zodiac are distinctly represented in two bands parallel to the axis of the building: six of the figures appear to be entering the temple on the eastern side of the portico, and of these Cancer is the last; the other six are placed in such a way as to be visible on the western side, so that the front of the portico being towards the north) the direction of their motion corresponds to that of the apparent diurnal rotation. Within the two lines of figures are those which belong to the northern constellations, and beyond the southern and western extremities of the portico, are figures relating to the southern constellations.

Among the former is a human figure surrounded by seven stars. Disposed similarly to that in the temple at Denderah, near to the temple of Isis, and the zodiacal signs, it has given rise to a doubt concerning the justness of that supposition. Some persons have imagined that the figure might have been intended for the mythological saraeaus; but as in this temple, as well as in those at Esne, it has significance in this case, the search has been made for evidence, in the stars represented that it suggests the zodiacal sign; and, that, according to the hypothesis of Biot, the displacement was in order to make room for some emblem. In fact, the place of Cancer is, in the portico, occupied by a head of Ibis, which is plumed in the solar rays; and, since Sirius was consecrated to Ibis, it is reasonable to suppose that the emblem was intended to express that, at the epoch of the planispheres, the star Sirius rose heliacally. By calculation it is ascertained that about 75 years before Christ, the longitude of Denderah, Sirius rose with the stars of Cancer, when the sun was in that constellation, that is, at the summer solstice.

The two temples at Esne have, in the ceilings of their porticos, representations of the twelve zodiacal constellations in two lines parallel to the axis of the buildings. In the smaller temple six of the figures appear to be entering on the southern side, and six to be issuing on the northern side: the front of the portico being towards the east, the direction of the movement corresponds with that of the diurnal rotation, as in the temple at Denderah; but there is this difference in the division of the figures, that, at Esne, Leo is the last to enter, and Virgo the first to quit the temple. M. Biot endeavours to account for this difference by the different inclinations which the axes of the two temples have to the meridian; the axis of the temple at Denderah deviating 17 degrees, and that of the small temple at Esne 71 degrees, both of them being from the north towards the east. He observes that, in the former temple, a meridian line passing through the centre of the circular planisphere cuts the zodiacal band in Cancer towards the north, and in Capricorn towards the south; thus dividing the twelve figures so that the one star are on the western side constitute all those which at a certain hour are descending towards the west, and the other six, which are on the eastern side are ascending towards the meridian. At the head of this descending series lies Aquarius, which is passing the upper meridian; the distribution of the signs from that point is the same as those in the zodiac of the portico. A like correspondence would be found to exist in both the temples at Esne, if a single planisphere were supposed to be placed in the risen of each, with the lotus-stem in the longitudinal axis, the zodiac is formed, and the planisphere were cut so as to divide the figures into such as ascend and such as descend.

That there were among the ancient Egyptians a number of fields in the spring; that at the average month since the planisphere described by Scaliger, in his "Raccolte," contained, among other animals have a correspondence in form or situation with those which have been mentioned, the figure of a man holding a scythe, that of a ram, and that of a bull, are to be found in the planisphere of the temple at Denderah, near to the temple of Isis; and those on the north side of the temple, or in the roof of the temple, which is placed in the tomb of that ancient king at Thebes, was 365 cubits in circumference, and to each cubit was assigned one of the 365 days of the year, with the rising and settings of the stars for each day marked on the several divisions.

The temple of the portico belonging to the temple at Denderah is nearly covered with sculptured figures, many of which resemble those in the circular planisphere, and the twelve signs of the zodiac are distinctly represented in two bands parallel to the axis of the building: six of the figures appear to be entering the temple on the eastern side of the portico, and of these Cancer is the last; the other six are placed in such a way as to be visible on the western side, so that the front of the portico being towards the north) the direction of their motion corresponds to that of the apparent diurnal rotation. Within the two lines of figures are those which belong to the northern constellations, and beyond the southern and western extremities of the portico, are figures relating to the southern constellations.

Among the former is a human figure surrounded by seven stars. Disposed similarly to that in the temple at Denderah, near to the temple of Isis, and the zodiacal signs, it has given rise to a doubt concerning the justness of that supposition. Some persons have imagined that the figure might have been intended for the mythological saraeaus; but as in this temple, as well as in those at Esne, it has significance in this case, the search has been made for evidence, in the stars represented that it suggests the zodiacal sign; and, that, according to the hypothesis of Biot, the displacement was in order to make room for some emblem. In fact, the place of Cancer is, in the portico, occupied by a head of Ibis, which is plumed in the solar rays; and, since Sirius was consecrated to Ibis, it is reasonable to suppose that the emblem was intended to express that, at the epoch of the planispheres, the star Sirius rose heliacally. By calculation it is ascertained that about 75 years before Christ, the longitude of Denderah, Sirius rose with the stars of Cancer, when the sun was in that constellation, that is, at the summer solstice.

The two temples at Esne have, in the ceilings of their porticos, representations of the twelve zodiacal constellations in two lines parallel to the axis of the buildings. In the smaller temple six of the figures appear to be entering on the southern side, and six to be issuing on the northern side: the front of the portico being towards the east, the direction of the movement corresponds with that of the diurnal rotation, as in the temple at Denderah; but there is this difference in the division of the figures, that, at Esne, Leo is the last to enter, and Virgo the first to quit the temple. M. Biot endeavours to account for this difference by the different inclinations which the axes of the two temples have to the meridian; the axis of the temple at Denderah deviating 17 degrees, and that of the small temple at Esne 71 degrees, both of them being from the north towards the east. He observes that, in the former temple, a meridian line passing through the centre of the
he constellation Cancer; and observing that Cancer is the last of the figures which appear to enter the portico of that temple, while in the zodiaca at Esna the lion is the last which enters, he conceives that the latter circumstance is an indication of the sun being in Leo when Sirius rose heliacally. Supposing further that the epochs of the zodiaca at Denderah and Esna are such as the positions of the sun denote, he determines, by a computation founded on the progressive displacement of the point of the heliacal rising, that the interval between them is 1300 years, the sculptures E For the priests change of the zodiaca, the latter must otherwise be considered as overthrown by the calculations of MM. Ideler and Biot, who have determined the longitudes of the sun at the terminations of three or four annal or regular periods of 1400 years, within which the ecliptic of Sirus return to the time of the summer solstice; and have found that between the year 2782 B.C., and 1300 B.C. the sun was in the constellation Leo and in the sign Cancer at all the three epochs. M. Biot concludes that the sun had passed from one constellation to the next in the interval between the epochs to which they are supposed to refer.

In the temple at Denderah, according to Dr. Young, Leo may have been the manner in which the Chaldean zodiaca, or the sign preceding that in which the sun was on the first day of the anuus vagon (year of 365 days); and in this supposition it would follow, from the known rate at which the place occupied by the sun in the ecliptic at the commence ment of its zodiacal season, that the fact that the year of 365 days began on the day of the solsticial epoch in the year 1300 B.C., that the epoch of the plane sphere is between 11 B.C. and 108 B.C., or in an age earlier by 1500 years. If Virgo were the leading sign, as is supposed to be in the temple at Esna, the epoch of the zodiac would be the year 900 B.C., or 1500 years earlier.

It has been ascertained by MM. Champollion and Rossellone, from the Greek inscriptions on the temples of Denderah and Esna, and in later edifices discovered in the same region, that the Egyptians continued to build temples, which they consecrated to their deities, with decorations similar to those which were executed in more antient times, it may be presumed that the present sculptured zodiacs are copies of those which were employed in the days of the emperors, that through they determine nothing respecting the time of the construction of the temples, they may still serve as indications of the manner in which the heavens were represented in the East in the infancy of astronomical science. The sphere which contains the interior of the temple at Denderah was brought to France in 1821.

The country from whence the Greeks derived the figures of the constellations is not with certainty known; so that all the extra-zodiacal signs in their descriptions of the heavens did not, from the first, receive their designations from subjects connected with the Greek mythology is evident, since in the notices given by the earliest writers on astronomy two of them, the distances of Halcyon and Cygnus, have the general names by πανον, a knoiling figure, and Ὑποκ, a bird; and that some of the figures were borrowed from the Chaldeans is probable, since in the time of Herodotus it was supposed that the constellation of the Pleiades arose from the Egyptian, the knowledge of the polus (στελη), the gnomon or style, and the division of the day into twelve parts. (Herod. ii. c. 109.) It may be imagined that, from the intercourse between the Egyptians and Greeks in very early times, they gave the same names to the signs of the zodiacs; and it follows, that those must have been introduced by the Greeks, or at least that the latter people substituted them for corresponding figures in the Egyptian sphere. It may be remarked however, that in the oldest descriptions of the Greek zodiac, χελωνης, the scorpion and the crab, make one constellation; whereas in the Egyptian zodiac the corresponding part of the heavens is divided between the scorpion and the balance, the latter occupying the place of the crabs. Now, in a work on the constellations, ascribed to Eratosthenes, who lived in the time of Ptolemy Euergetes, it is stated that the great length of the constellation Aquarius caused astronomers to divide it into two parts; and in a poem attributed to a certain Manetho, supposed to be the priest of that name, and dedicated to one of the Ptolemies, it is expressly stated that 'the claws of scorpio were given to Menes, the last Pharaoh of the eleventh dynasty; whereas the Egyptians, on or before the time of the great antiquity of the sign it may be observed that, in that shape, the Chaldean designation, signifying a balance the constellation called by the Greeks χαλκος; it may be however, that he alluded then to the Chaldeans of his own time.

The designations which are given to the constellations in the writings of the Greeks apparently indicate persons or objects connected with the Argonautic expedition; and it is reasonable to suppose that, about the epoch of that expedition, the Greeks, having acquired a knowledge of the Chaldean zodiaca, supposed that the figures represented the visible heavens, transformed such of the figures as they did not reject into others having relation to the actions of their own heroes. On this hypothesis it has been assumed that Arius represents the ram whose horns were tied to the head of the bull or bulls which were tamed by Jason; Gemini, Castor and Pollux, and so on. The ship, among the southern constellations, is supposed to be the Argo; and Ursa Major, the nymph Callisto. The history of Perseus has been employed by Chiron, Andromeda, Cepheus, Cassiopeia, and Cetus; and the labours of Heracles, by Draco, Leo, and the constellation bearing the name of that hero. Newton, in his 'Chronology,' appears however to assume too much when he considers that this zeon, when he built the Argonautic expedition, the stars of the constellations, supposed Arius, Cancer, Libra, and Capricornus so that the equinoctial and solstitial colures passed through their middle points; the precise determination of these parts was beyond the science of the Greeks long subsequently to the age of Chiron.

Hesiod mentions (Opera et Dies) the Pleiades, Arcturus, and Orion, stating that land should be ploughed at the heliacal setting, and corn reaped at the heliacal rising of the Pleiades (about the 20th of April), and that corn should be threshed at the rising of Orion, and vines pruned when Arcturus rises in the evening. Homer also mentions the Pleiades, Hyades, the Bear or Wagon, and Orion in the description of the shield of Achilles (II. xviii. 497); it is evident therefore that already in the time of Homer those constellations were introduced and ranked (that is to say, in the 7th or 8th century B.C.,) and that the name of that constellation on the poem of Aratus: planispheres, he observes, are constructed for men's use, and therefore the names on them are traced just as they appear in the heavens to the view of the spectator.

In the work of Autolycus, entitled 'On Rises and Settings' of the Stars (Περὶ Ἑντολῶν καὶ Διστολῶν), and in the 'Phaenomena' (Φανοματα) of Euclid, the signs of the zodiac are mentioned, and the parts into which that band of the heavens was divided are called dodacemotories, or twelve disciples; but it is evident that the most complete knowledge of the celestial sphere of the Greeks is to be obtained. This writer lived about 270 years before the Christian era, and his poem is a paraphrase of two works which were composed by Eudoxus of Cnidus, who lived 100 years previously, that is, in the age of Autolycus and Euclid.

In describing the constellations, Aratus begins with those immediately about the north pole of the equator, and proceeds from there (that is, near) the north pole, in the directions of the declination or hour-circles of the sphere.
He mentions Ursæ Major and Ursæ Minor, observing that they are placed so that the tail of one corresponds to the shoulder of the other, and he adds that the constellation Draco winds between them. Near the head of Draco he places the figure of a man, who is said to be on his knees (Heracles, his usual attitude, has since been changed, and) behind him the northern crown. Near the kneeling figure is Ophiuchus, the serpent-carrier, and under the latter are the great claws (of Scorpio). Behind Ursæ Major is Cepheus (Boötes), with stars below his girdle, and under his feet is the constellation Virgo. Near the head of Ursæ Major are Gemini (Διήπεδος); under his body is Cancer, and under his feet Leo. Auriga and the star Capella are said to be on the left of Gemini, opposed to them being the right hand of Auriga and horns of Taurus, whose head is indicated by a cluster of stars (the Hyades). Cepheus is behind Ursæ Minor, and near him is Cassiopeia, the stars of which are said to be arranged in the form of a key: Cassiopeia has her hands raised above her head as if bewailing the fate of her daughter Andromeda, who is placed below her. The arms of the latter are extended and chained (to a rock); and under her head is Pegasus. Ariës is below the girdle of Andromeda, and as well as the claws of Scorpio and the girdle of Taurus, is in the equator and is above Ariës. The constellation Pisces is below the triangle; and Perseus stands with his hand near the chair of Cassiopeia. Below his left knee are the Pleiades, and the nine stars of the daughter of Atalanta are given to the stars of the cluster. Antares is near the head of Perseus, and six stars in the cluster; but Hipparchus, in his commentary on the poem, states that against a dark sky seven may be seen. The Bow of Sagittarius tends towards the tail of Scorpio, and the point of which carries the sign of the zodiac, which is represented by a girdle between Perseus and the head of the bird (Σετλαν). This is the constellation Cygnus, which also by Manetho and Ptolemy is called the Bird. The name (Cygnus is first applied to) a work on the constellations which is ascribed to Claudius Ptolemy. Cygnus extends towards the other eagle (Aquila), and near the head of Pegase is the right hand of Aquarius, which, it is remarked, rises before Capricornus. Over the latter is the Dolphin. All the above constellations are stated to be between the zodiac and the equator, six are given as the girdle of the ship Argo, and afterwards mentioned in order, beginning with Cancer and ending with Gemini. Libra (elsewhere called Στεφνα) is not mentioned, while Scorpio and the Claws are described as if they formed two constellations.

A description of the constellations between the zodiac and the south pole, it is stated that Orion is placed obliquely to Taurus, and that Canis Major is at his feet. Under him is said to be Lepus, and at the tail of the dog. The head of the ship Argo is in Pisces, and above the river (Eridanus), Cetus advances towards Andromeda, and below Capricornus is the Southern Fish. Under Sagittarius is a circle of stars (the Southern Crown), and below the sting of Scorpio is the A. Under the Scorpion is Centaurus, while farther on is Hydra, having its head under Cancer, and its tail above Centaurus; and the middle of its body is Crabes, and near the tail is Corvus. The bright star Procyon is under Gemini.

Such, nearly, is the description given by Aratus of the celestial sphere, and the constellations are, in general, the same as those which are represented on the modern globes: some inconsistencies which exist in it were pointed out by Hipparchus, who lived about 100 years before Christ, and who corrected the figures of the sphere. Very plain that the descriptions have been compiled from observations made by persons at different places, and probably in different ages; for in one part of the work it is stated that the extremity of Ophiuchus is in the tropic of Capricorn, and in the other it is the girdle of Cepheus. It touches the horizon; while in a third the three girdles of Boetes are to go below that circle, except his hand; and these circumstances are quite in conflict with observations made in the same latitude. It should be remarked that, in the Generation of the world as represented in the mosaics of the ruins of the Temple of Artemis, and in the relief of a table of the Zoroaster) that the ancient Persians divided the zodiac into twenty-eight constellations, or houses of the zodiac, and also into twelve signs: to these last are assigned the names which correspond to those at present given; and the constellations in that region of the heavens which is described as that
The division of the zodiac into twenty-eight lunar mansions prevailed also among the Arabian astronomers in or before the ninth century. It is mentioned by Alfragan, who states (Elementa Astron., A.D. 50) that the first was called Xartan, and that it contained the three principal stars in Aries.

The Hindu zodiac consists of twelve constellations, the same as the Philosophsic Transactions' for 1772, consists of twelve figures disposed on the four sides of a square. In this the place of Gemini is occupied by a figure of a man apparently with a ram's head, the bull, the ram, and the lion are represented by figures which are frequently placed in the普通的 plate presents Aquarius; and for Pisces, one fish only is delineated. The figure in the place of Scorpio cannot be made out. This remarkable monument was discovered in the ceiling of a church or pagoda at Verdapotthia, in Madura; and the separation of the figures in Capricorn seems to indicate that it is of great antiquity, as it may be reasonably supposed that such a disposition preceded in time of that of a union of the two bodies in one.

In the second volume of the Asiatic Researches there is a description from the Sanscrit of Sirjelti, of an antient zodiac, which is divided into twelve parts, each of 30 degrees, corresponding to the modern signs. The ram, the bull, the fish, the zodiac signs may be clearly seen, and those of those animals, and in the plate which accompanies the memoir the entire figure of the bull is given: the twins consist of a male and a female figure, and in the description, the woman is said to play on a musical instrument, while the man is shown chasing her, and that they are not so represented in the plate. Virgo is represented by a woman in a boat: in one hand she holds a lamp, and in the other a blade of corn. Libra is represented by scales, which are held by a man who appears to be placing a weight in one of the pans; and the pans may be considered as those of a horse. Capricornus is the figure of a gazelle. Aquarius is represented by a man pouring water from a vessel which he carries on his shoulders; and lastly, Pisces, the figure of two fishers, one being turned towards the tail of the other. The zodiac is also divided into twenty-seven parts, constituting the mansions of the moon: these are not represented in the plate, but their names, as well as those of the twelve signs, are given.

The age in which Sirjelti lived is unknown.

The zodiacs of India and of antient Persia may be presumed to have been originally the same as that of the Greeks or Egyptians; for although all of them differ from one another in the details, the points of coincidence are too great to be accidental, and the course of the time the primitive sphere was altered in the countries eastward of Egypt and Chaldea, as it was by the people of Europe. On the subject of the Indian zodiac the reader may consult Bohlen, 'Das Alte Indien,' vol. ii., p. 232, &c., and the references in the notes.

The representations of the heavens which have been found among the people of northern India, China, and Japan correspond to those which were in use in the western part of Asia, and the zodiac being divided into twelve parts, which are called mansions of the sun, and also into twenty-eight parts; but, according to the accounts of the Jesuit missionaries, the Chinese at one time gave to these the names of the seven planets, each of which was repeated four times. Thereafter, the names of the twelve signs frequently made of machines exhibiting the apparent movements of the heavens; and Père Mailia has given a plate representing a sphere which is supposed, though without sufficient reason, to have been executed about the year 1300. But, if the Chinese were, at a time long subsequent to the commencement of the Christian era, instructed in astronomy by a people from the west; and it is therefore probable that they then were a long time the lowest of the Persians and Arabs in the division of the zodiac.

A table of the twenty-eight constellations into which the Chinese have divided the zodiac, with their names and the extent which each occupies, is given in Delambre's Histoire des sciences, i. p. 369, from the work of Père Souciet entitled 'Observations Mathematiques, Astronomiques,' &c. 1729; and it is stated that the first, which is named Pi, commenced, in 1683, with the fourth degree of Aries. Delambre has also given a table of the twelve constellations; and from the records of the eclipses which the Chinese have observed, it is evident that the place of the sun has always been referred by them to the sign of the zodiac which he occupied; and period they made their year commence when the sun is near the winter solstice, and they designated that part of the zodiacal resurrection the spring, or of the sun in the bull, the scorpion, the serpent, the horse, the sheep, the ape, the hen, the dog, and the hog are names supposed to be given, both in China and Japan, to the zodiacal signs; but it is more probable that they are applied to the twelve years of a person's life, according to the time which the sun requires to change five hours into which, in those countries, the day is divided.

The extra-zodiacal stars are distributed in constellations, which are distinguished in general by the names of the emperor and his ministers or courtiers; but that which in Europe is designated Ursae Major is represented by a vessel for measuring corn; the four stars of the quadrilateral figure forming the body and the others the handle. But relates, from information communicated by M. Remusat, that in the Chinese sphere the constellation which corresponded to Orion is designated by a name signifying a conqueror.

That a few coincidences should exist among the names given by different people to the groups of stars in the heavens is supported by the fact that the people borrowed from one another; it may therefore be considered as purely accidental that the Iroquois called the stars of Ursae Major by a name which in their language signifies a bear (Lafitteau, Moeurs des Amér. sauvages, p. 20), and that they have been connected with the stars of the same name, if not separated, by the former should have executed sculptured representations of their calendar, and placed them as ornamental objects in their religious edifices. It has been ascertained that the Toltecs and Aztecs made the year consist of eighteen months of twenty days each, to which they added five complementary days, introducing a period of thirteen days at the end of fifty-two years in order to complete the cycle; and this division of the year is represented in a chronological table executed by the latter people (Carreri, Giro del Mondo.) Among the ruins of Palenke have been found sculptured figures of serpents, which have been thought to indicate the existence of the Ophtie worship in that part of the country, the seat of the Toltecs; and at Tula, the seat of the Aztecs, there is a monument supposed to be a planisphere, on which are eighteen compartments representing months, which are disposed three together in the interior of a ring ornamented with hieroglyphic figures. In 1790 there was discovered in the city of Mexico, among the foundations of the temple of Mexitli, a block of porphyry, on which are described symbolical figures, apparently constituting a planisphere or a chronological table, in which the several days of the year are distinguished by particular names and objects, and a few of them are stated to correspond nearly to the signs on the Chinese planispheres. M. de Humboldt remarks (Researches, &c.) that the name of the first day is also the name of water, and that the symbol of the day resembling more closely that of Aquarius in the Greek and Egyptian zodiacs.

ZODIAL LIGHT, a luminous appearance seen at certain times after sunrise and before sunset, from which it is inferred that there is a slight disturbance of the air, arising from the denser parts of that medium which (Comet) is more than conjectured to occupy the spaces in which the bodies of our system move.

A few months ago, when the comet of this year (March, 1843) was visible in lower latitudes, its tail only appearing (except for a very short time) above the horizon in England, some persons contended that this tail was only the zodiacal light. This produced a letter from John F. H. H. Stewart, in which a description of that light was given. We have before expressed
our opinion that celestial phenomena should be described in the words of those who are observers themselves. We therefore subjoin the following extract from the letter in question:—'The zodiacal light, as its name imports, invariably appears in the zodiac, or, to speak more precisely, in the plane of the sun's equator, which is 7° inclined to the zodiac, and which plane has an angle of 1° 25' from the sun, intersected by the ecliptic in longitude 28° and 258°, or so much in advance of the equinoctial points. In consequence it is seen to the best advantage at, or a little after, the equinoxes, after sunset at the spring, and before sunrise at the autumnal equinox, being visible only because the line of its apparent axis lies at those times more nearly perpendicular to the horizon, but also because at those epochs we are approaching the situation when it is seen most completely in spring.'

At the vernal equinox the appearance of the zodiacal light is that of a pretty broad pyramidal, or rather lenticular, body of light, which begins to be visible as soon as the twilight decays. It is very bright at its lower or broader part near the horizon, and (if there be broken clouds about) often appears like the glow of a distant conflagration, or of the rising moon, only less red; giving rise, in short, to amorphous masses of light, such as have been noticed by one of your correspondents as possibly appertaining to the comet. At higher latitudes its lighter and broader, and it is more clearly traceable much beyond the Pleiades, which it usually however attains and involves; and (what is most to my present purpose) its axis at the vernal equinox is always inclined (to the northward of the plane of the ecliptic) at an angle of 1° 25' below the horizon; and it is most luminous at its base, resting on the horizon, where also it is broadest, occupying, in fact, an angular breadth of somewhere about 10° or 12° in ordinary clear weather.'

ZOEÁ. [BRANCHODOPA. p. 339.]

ZOEÁ, GEORG, was the eldest of the three sons of a Lutheran clergyman of Jutland, said to have been of Italian name, but who was born at Roskilde, December, 1736, at the village of Dahlen in the county of Schackenburg and the diocese of Ribe, where his father was then minister, although he soon after removed to the parish of Møgel-tonder, near the town of Tonder in the same county. After having been carefully educated at home, under the eye of his father, Zoega was sent, in 1772, to the gymnasium of Altona, whence the next year he proceeded to the university of Göttingen. On finishing his academic course, in 1776, he set out on a tour through Germany and Switzerland, which he was eventually led to extend to Italy, and he did not return to his native country till he had visited both Venice and Rome. He then passed a winter at the university of Leipzig; after returning home from travel spent some time in the office of a brother of his father, who had a seat under the government at Copenhagen; but at last, in October, 1778, he accepted the situation of a family tutor in the little town of Kierte-minde, on the eastern coast of the island of Fünen. After a few months however he was offered the appointment of travelling tutor to a young gentleman who proposed to make the tour of Germany, Italy, France, and England; this scheme exactly suited the taste of Zoega, who was already devoted to the study of the fine arts. After a year's residence with his pupil at Copenhagen, where he eventually conceived an intimacy with his old professor Heyne, with whom he had been always a favourite, they set out together in March, 1780, and after having visited Cassel and Frankfort, and traversed Hesse, the Palatinate, Suabia, and Bavaria, went down via Cologne to Venice, where he concluded the study of art, and Carinthia to Venice, whence they proceeded through Lombardy and Tuscany to Rome, and from Rome to Naples. Returning to Rome, they spent two months more in that city; and then, in May, 1781, were about to take the departure thence for the Campania; but the king of France, on an unexpected death suddenly recalled them to Denmark. Soon after his return home Zoega was introduced to the Danish minister Guildborg, who, struck with his mellow voice, proposed to make him to take the charge of the king in Germany and Italy. Upon this enterprise he set out in April, 1782; and after spending six months in the Imperial Museum at Vienna, he arrived once more at Rome, in January, 1783. From this date Italy, and chiefly Rome, continued, with the exception of a short visit which he made to Paris in 1784, to be the residence of Zoega to the end of his life. The sudden death of the patron Guildborg, the news of which reached him, was at Paris, in May, 1784, reduced him for a time to great straits; and his difficulties were made the more serious by his having some time before both disobedience and desertion of a young Italian, named Pietruchini, a most beautiful but penniless daughter of a painter, and became convert to popery. He had however on the introduction of the Austrian papal nuncio Garumph, whose acquaintance he had made at Vienna, been received with distinguished favour. Favour was particularly obtained for him at the Propaganda College, afterwards cardinals; and he was through Borgias's interest, received from the pope the appointment of interpreter of modern languages to the Propaganda College. He now prolonged the preparation of a critical catalogue of the series of Egyptian coins issued by the Roman emperors, mostly as contained in the old museum of Borgia at Vellutari, which was last published in 1795. At Rome, in 1797, with the title of Numer Zuœ Georgen Imperatoris probatissimi in Museo Burgiano selua spectantes quotquot religios usus classica ad varia musae atque libris colligere obtiti. This attracted great attention, and soon made the name of Zoega known throughout Europe. It was followed by another work on the numismatics of the money of Rome, celebrated by the desire of Pope Pius VII., and the printing of which, he had been going on for five years, was at last completed in 1797. But after the labours and anxieties of so many years, which pressed the more heavily upon Zoega as he was by nature a most active and restless man, his health was much better than 10° to 70° below the horizon; and it is most luminous at its base, resting on the horizon, where also it is broadest, occupying, in fact, an angular breadth of somewhere about 10° or 12° in ordinary clear weather.'
a have amounted to 900 crowns; but then it was paid in 
sterling, and the Danish paper-money at this time, and still 
more at a later date, was much depreciated. Zoëga's next 
work was a catalogue of the Copic MSS, in the library of 
archbishop Borgia: 'Catalogus Codicum Copicorum in 
manuscriptu quin Musaeo Regiorum Valiae adscriptis: 
uctore Georgio Zoëga. Dano, Equite Aurato ordinis Dano-
rigoci, f., Romae, Typis Sacrae Congregationis de Pro-
agudae Fide.' The whole of this work, with the excep-
tion only of three pages, is original, and was printed in 1633, 
at the request of Cardinal Borgia, who took possession 
that Lyon in the end of 1604, and the embarrassment into 
which Zoëga was thrown by that event, which involved 
im in a lawsuit with the heirs of the cardinal and the producer, 
the whole of which is stated in notice of Zoëga, by 
father, but it was not published. We have reason to 
believ that Zoëga died in 1810, after his decease, when the case was 
decided in favour of his children. Meanwhile he had commenced, in 
conjunction with Piranesi and the engraver Piroli, an 
catalogue of the plates in the Museo Aurelianum at 
Rome, the first 4to. volume of which, published 
in numbers, was completed in May, 1508; a 
second volume was carried on for some numbers by Zoëga, 
without the assistance of Piranesi, but was left unfinished 
by his death. Zoëga wrote an account of his travels, in 
1781-1812, by F. G. Wecker, then professor of 
Greek in the university there, with the title of 'Die 
Antiken bas-reliefe von Rom. In den originalpapierschatzen von 
Thomas Piroli in Rom, mit den Erklärungen von Georg Zoëga, 
verfaßt, als Zoëga's Notice of his death, received in 
the Biographie Universelle, vol. lii., 
1784-1808, from which, and from his works, the facts in the 
recording abstract have been taken. The work on 'Egyptian 
Antiquities' in the 'Library of Entering Knowl-
dge' for 1808, published by 
Orellans and his labours on the hieroglyphics. Besides 
his exact and extensive learning in every branch of archae-
ology, including Egyptian as well as Greek and Roman 
antiquities, Zoëga is held in the highest esteem for his 
accurate and impartial judgment. In his writings, and in 
his speeches, he was distinguished for the truth with 
which he had seized the spirit of antient art. 

ZOFVANNY, JOHANN, R.A., a very distinguished 
sculptor of the latter part of the eighteenth century. He 
as by descent a Bohemian, but his father, who was an 
archbishop of Rome, settled in England. He was born, 
according to Firillo, at Regensburg in Bavaria, or, 
according to another account, at Frankfort on the Main, 
in 1753: the latter probably is the correct account. Young 
offany was sent early by his father to Italy, where he 
studied sculpture. In defence of the work which he returned to Germany— 
passing some time as an historical and portrait painter at 
oblenz on the Rhine, from which place he came to England 
seven years before the foundation of the Royal Academy, 
he was elected one of its first members, in 1768. In 
character he was probably a warm-hearted man, attracted 
to him, and his first pictures which attracted notice 
London were a portrait of the Earl of Barrymore and 
three theatrical portraits. He painted Garneck in Sir John 
ate, and as Abel Dragger in Boswell's 'Alcy-
ony.' Footes, in the 'Mayor of Carrell,
ston and Foote in Dr. Last; and Garrick in 
the Farmer's Return,' in which the character and drawing 
are very good; the colouring is less successful. 

For his work on 'Am Phraem.' 1, XV., 
large canvas, to the number of ten portraits, which has been 
scraped a mezzotinto by Earlon. He painted likewise two 
separate portraits of George III. and his queen, which were 
engraved in mezzotinto by Houston. Shortly after this 
time he revisited Italy, and took a recommendation from 
George III. to the Grand-Duke of Tuscany at Florence, 
where he painted an interior view of the Florentine picture-
gallery, which was purchased by George III. In 1774 he 
wanted a clever picture of the 'Lute-school' of the Royal 
Academy. In 1781 and 1782 Zoëffy went to the East Indies, 
and lived some years at Lucknow, where he met with the 
greatest success, and he painted three of his best works 
there, all of which have been well engraved in mezzotinto 
by Earlon. One is the Embarkation of Hyderbac to Cal-
cutta, who was sent by the Vizier of Oude to Lord Corn-
wallis; he went with a numerous retinue by Patna to 
Calcutta: the picture is a rich display of Indian costume, 
and contains, besides 180 figures, several elephants and 
horses; the scene is placed in India. The others are an 
Indian Tiger-Hunt; and, as a companion to the Emb-
assy, a Cock-fight, at which there are many spectators. 

Zoëffy returned to London, about 1796, with a large 
stock of pictures, and died at Earlon in 1806. (Firillo, Geschichte der Malerheilk, &c.; Pilkington 
Dictionary of Painters.) 

ZOILUS (Ζωίλος), a Greek rhetorician and grammarian, 
is called by some a native of Ephesus (Scholast of Hom. 
Homer., v. 7), though he was not domiciled there, but 
as a youth of about 360. Vitruvius ('Prost., lib. vii.,) on the 
another hand, makes him a contemporary of Ploemey Phil-
adelphus, n. c. 293-247. Suidas (v. ων τονεπηαδος) states 
that Anaximenes of Lampacus was a pupil of Zoilus, 
and Philodamus, and had written a work on dialectics, 
which was prescribed by the law of Macedonia after 
the time of Alexander the Great. These different 
statements of the age at which Zoilus lived do not allow 
us to draw any more definite conclusion than that he must 
have lived during the period that followed the death of 
Alexander the Great. We have thus no alternative but 
to suppose that there were two persons of the name, 91 Zoilus—that was the 
name of a rhetorician who attacked Homer, and the other a 
grammarian who attacked Homer, and the other a 
rhetorician, though a careful examination of the passages 
in which Zoilus is mentioned leaves no doubt that they all 
refer to the same person. We have thus no alternative but 
to suppose that there were two persons of the name, 91 Zoilus—that was the 
name of a rhetorician who attacked Homer, and the other a 
rhetorician, though a careful examination of the passages 
in which Zoilus is mentioned leaves no doubt that they all 
refer to the same person. We have thus no alternative but

name of a rhetorician who attacked Homer, and the other a 
rhetorician, though a careful examination of the passages 
in which Zoilus is mentioned leaves no doubt that they all 
refer to the same person. We have thus no alternative but 
to suppose that there were two persons of the name, 91 Zoilus—that was the 
name of a rhetorician who attacked Homer, and the other a
land. His early education was conducted by his father, a distinguished and much respected lawyer; and after having for some time attended the public school of his native place, young Zollikofer was sent to the gymnasium of Frankfort on the Main and of Bremen. When he had completed his preparatory courses, he went to the university of Utrecht, where he studied chiefly theology, but devoted also much time to the study of the antients, of philosophy, and belles-lettres. Soon after his return to Switzerland, he was appointed, in 1793, pastor at Maria-Therianspol, in the Pays de Vaud, but he did not remain there long. After having successively been removed to Monstein and Isenburg, he was invited, in 1798, to the office of pastor of the Reformed (Catvinistic) congregation at Leipzig. In that place he continued until his death, on the 20th of January, 1789, although several very honourable offers were made to him. His position at Leipzig was particularly favourable, for his congregation was one of the most enlightened in Germany, and his intercourse with the distinguished professors of the university had a great influence on the development of his talent as a pulpit orator. He also exerted a very beneficial influence not only upon his congregation, but upon the young theologians of Leipzig, to whom his upright and pious conduct was a manifest example. His knowledge, though very extensive, was not always profound, and he attached a higher value to the practical part of religion than to learning and theological speculation. He taught his flock by word and example, and from both of these sources he distributed the rich harvest of his private study and reflection. His method of preaching was always calm and dignified, impressive and convincing without being rhetorical. Although his sermons were not exactly what we call popular, they were always clear and luminous, as his way of teaching went through the heart and not the head. He counteracted the prevailing prejudices and evils of the time, and endeavoured to correct the vulgar notions of morality, and to enlighten his audience in the true sense of the word. What rendered his influence as a teacher of principles so strong, was, at the time, a perfect exemplar of what he taught. As regards his doctrinal views, he did not hesitate to attack the common opinions where he thought them incompatible with reason and goodness; and, although he was not a neologist, yet he maintained several points from the committee of the Calvinistic view. The best of his sermons, amounting to about 250, were published and received with great favour, and they are still much read in Germany. Zollikofer himself published several collections of sermons, in 4to, 8vo, 1771-1793, 3 vols. 8vo, in a second in 1784, 2 vols. of which a third edition appeared in 1789. After his death a collection of unpublished sermons was edited by F. von Blumenbach, Leipzig, 1798, 15 vols. 8vo, from which two more volumes were added by J. G. Marezoll, Leipzig, 1804, 8vo. About the same time there appeared a complete collection of all Zollikofer's sermons, in 15 vols. 8vo, Leipzig, 1789-1804. Besides these sermons, he published: 12 sermons, books to the Reformed Churches (Leipzig, 1766, 8vo), some of the hymns are of his own composition, and the great popularity of them is manifest from an eighth edition being published in 1789, 8vo. 2. "Abhandlung über die Erziehung," Leipzig, 1783, 8vo. 3. "Anreden und Gedichte zum Gebrauch bei dem gemeinschaftlichen und auch dem hüttenischen Gottesdienste," Leipzig, 1777, 8vo, reprinted in 1783. 4. "Anrathuisungen und Gebote zum Privatgebrauch für nachdenkende und gutesgeseunte Christen," Leipzig, 1785, 2 vols. 8vo. A fourth volume appeared in 1790, 2 vols. 1792 and 1793, and a new edition of the two last volumes in 1802, &c. Zollikofer also translated several works from the French and English, with which languages he was thoroughly conversant. For the English he translated P. B. Crolius' "Traite," 3 vols. in parts, and have a third edition appeared at Leipzig in 1783. Zollikofer's sermons were translated into English by William Cooke, 10 vols. 8vo. (Cf. to Zom," Uber den Character Zollikofers," Leipzig, 1798, 8vo.; "Jürgens, Lexikon Deutscher Dichter" und "Prosaisten," pp. 603-690.)

ZOMBOR, an imperial free town, in the county of Baez in Hungary, is situated in 45° 49' N. lat. and 15° 12' E. long.; at a distance of 2 miles from the Danube, and 23 miles from Maria-Therianspol, in a plain on the banks of the Francis Canal. It contains 3500 houses (most of them low and covered with thatch), and 22,000 inhabitants, of whom about 12,000 are schismatic Greeks and the remainder Roman Catholics. The latter have a large majority of converts, some being of the Francis Canal, and given to the Roman Catholics by his imperial predecessor, Emperor Francis I. The Greeks have two churches and a chapel. The principal public buildings are the castle, the very handsome county-hall, which was completed in 1784 and was reprinted in 1793, and a parish church on the town-hall, likewise a handsome building, the grounds of which are a large quadrangle of buildings, containing the office of the royal commission for the management of the affairs of the town. There are good Roman Catholic schools in the town, a seminary for schismatic Greeks and Illyrians. There are many noblemen resident in the town. A great number of the inhabitants follow various mechanical professions. The trade of the town is very great, chiefly in corn and cattle. There is a great facilitate of the Francis Canal, which unites the Danube and the Theiss, and is nearly 70 miles in length. It was opened in May, 1802. This canal shortens the distance between the Danube and the Theiss by 20 miles.

ZONARAS, JOANNES (Iouanēs Zonaras). Geneseis ('Generale Historia'). A history of the time from the Creation to the Christian era. He was a native of Constantinople, and lived in the reign of the emperor Alexius Comnenus. He was at first invested with the high office of private chamberlain of the emperor's body-guard, and that of protostraton, and from that position he rose to the rank of grand vizier. During this last period of his life, which falls in the time of Johannes Comnenus, he devoted himself to the publication of his history, and to the production of several great works of a historical and partly theological character. He is said to have been acquainted with all the affairs of the Eastern world, and his contemporaries, as well as by subsequent writers, terms of the highest praise, both as a scholar and a writer. He subjoins a list of those of his works which have been printed, and begins with the most important. 1. "Monumenta Graeca," 1729, 3 vols. 8vo, in the Bonn collection. His history was written in Greek, and translated into Latin by J. Quatremere, Paris, 1558, and 1672, and 1672, 1608, &c. and then printed in the Venice collection of the Byzantine history, 1729, 8vo, in 23 vols. fol. In the Bombay edition of 1792, of the Zonar's commentary, both in Greek and Latin, was printed by G. Beuerburg, Oxford, 1672, fol. G. Beuerburg, Oxford, 1672, fol. 8vo, is an exposition of the sacred text and those of the apostles, councils, synods, and ecclesiastical fathers. The Greek original of the latter, with the Latin translation, was published in 1672, and from that in whole or in part. Zonar's commentary, both in Greek and Latin, was printed in Greek in Coblenz, "Monumenta Ecclesiae Graecae," ii, p. 343, &c. There are several other works of Zonar, and among them are several homilies and letters which have not yet been printed, only in a fragmentary way: a complete list of them is given by Fabricius.
ZON 

(Biblioth. Greec. xi. 222, &c.; vii. p. 465, &c.; compare Cave, Historia Literaria, i. p. 648, &c.)

ZONE (the Greek Zong, a belt), a portion of a sphere intercepted between two parallel planes. When, on the globe of the earth, one plane is the equator, and four others are drawn parallel to the equator, two of which contain the circles in which the sun is vertical at the summer and winter solstices, and the other two, the circles of which are as far distant (on the earth) from the poles as the former are from the equator. A zodiacal belt is called the north and south frigid zones: throughout these zones the sun never rises during a part of the winter, and never sets during a part of the summer. The parts intercepted by the equator and meridian are called the southern and northern temperate zones: in every part of these there is always rising and setting of the sun for every day in the year; but in the polar regions all parts are dark six months of the year and six months illuminated. The torrid and frigid zones deserveth their names; but the temperate zones partake of both excessive heat and cold in those parts which are near the boundaries of the torrid and frigid zones. Every zone, in fact, paradoxic fold is the same; but the parts which are near the boundary of one zone and are far from the other are very different. The parts which are near the same boundary, and which are far from other zone boundaries, are generally called the zone. 

ZONOTRICHIA, Mr. Swainson's name for a subgenus of Fringilla, arranged by him in the subfamily Fringillinae, the family Passer. 

Subgeneric Character—Bill as in Fringilla; the comb unusually strong. Wings not lengthened; the first quill longer than the four next, which are of nearly equal length. Tail rather lengthened, slightly divided; the outermost feathers the longest. External toes slightly unequal. Tarsus and middle toe of equal length. America only. (Sw.)

ZONURUS, Merrem's name for a genus of Saurians, has been defined by Mr. J. E. Gray:—

Generic Character.—Lizard-like; ears exposed. Legs short; femoral pores distinct. Head depressed, broad behind, supra-orbital plate expanded. Tail depressed, with the exception of the five terminal annulated spiny scales. Back with imbricated subaponeurotic, belly with smooth scales. Five toes on each foot.

Geographical Distribution.—Old World. 

Mr. Swainson, who gives this character, and places the genus in his family Lacertidae, Long-tongued or True lizards, remarks, in his Classification of Reptiles, that fr. Gray's definition of this group makes him conclude that it is to be the exact representation of Stelloa among the thick-thonged lizards; but, as Mr. Gray brings within the same genus, &c., which does not include all the above definition, the subgenus, or type of Zonurus, is fearfull of being inserted into the minor divisions.

Mm. Duméril and Bibron arrange the genus under their subfamily, Physiophragmocnus, of Chalcidiznidae, and thus characterize:—

Tongue arrow-point-shaped, free on its anterior half, and only notched at the end, its surface velvety. No teeth in the palate. Maxillary and intermaxillary teeth equal, osselated, simple, blunt, qd against each other. Notostrals internal, both pierced in a central plate—the naso-rostral. Elytra. tympanic membrane expanded on the border of the auricular aperture. Four great parietal plates forming square, at the centre of which is the interparietal. Four set, each three-centred, of the naso-rostral plates, forming an unequal, slightly compressed, and carinate emargination below. Femoral pores in one, two, or three rows.

Mm. Duméril and Bibron observe that the Zonurus have a physiognomy which calls to mind that of the Steinfusill ut and Agamen. Their head is triangular, flattened, and wider than the neck; their trunk is short and depressed; their sides are enlarged, and arched from before backwards; their limbs are robust, offering a development proportioned to that of the other parts of the body; their tail is stout and of moderate extent. The tongue of the Zonurus has the same form as the true lizards, of an arrow-point shape, that is to say, it is narrowed in front, whilst on the opposite side it is wide and divided into two, so as to represent a fork or the branches of a Y, between which is situated the orifice of the trachea. The posterior extremity of the tooth on the upper part, and has a very slight crescentic notch. Its surface is covered with small, straight, filiform papillae, more or less short, placed close to each other so as to produce a velvety surface. In the Zonurus the jaw contains forty, which are equal, conical or subadultrical, with a simple and blunt summit. The upper surface of the head of these cyclosauria is a true oaceous buckler, furnished with plates, which, in number and disposition, preclude a different classification. There are some differences in the parts of the head and skull, but which are not marked. The cephalic plates of the Zonurus consist of one rostral, two naso-rostral, one inter-naso-rostral, two frontal-inter-naso-rostrals, one frontal, two fronto-parietal, four large equal quadrilateral parietals, together forming a square, at the middle of which is situated an and, the size of which, as the width of the plate, resulting from the disposition of the four parietals, is bordered on the right and left by three plates—the parieto-temporals—the two first rectangular and the third nearly square. There are, as in the lizards properly so called, four plates, one on each side, situated under the inter-parietal region itself is invested with three or four oblong plates. The external orifices of the nostrils are pierced, one on the right, the other on the left, at the extremity of the muzzle, at the summit of the frontal region, in a single line; the organs of smell are divided behind which are situated four lateral points in the skin, one above the eye and a small one below, and a very large one below, which the globe of the eye; the slit is longitudinal, but a little inclined forwards. The two are unequal; on the anterior extremities, the first toe is the shortest, the fifth comes next, then the second, and finally the third and fourth, which are of the same length. On the posterior extremities the four first toes are regularly graduated; the fifth, which is inserted very far back upon the tarsus, has its anterior extremity on the same line as the fourth, and the latter in the same line as the third, and again there are instances where it is invested by aculezeichnet granules. In general there is a small cutaneous fold in front of each shoulder, descending in an oblique line upon the middle of the edge of the breast, where it results in a carina, as in case of one species, Acanthodactyli. All the species of Zonurus have the lower surface of the thighs pierced with large pores, disposed either in a single row, in two, or even in three. In many there is, on each side, between the belly and the side, a rather deep furrow lined with granules. Sometimes the upper part of the neck and back have a sort of cuirass composed of quadrilateral scales in juxtaposition or slightly imbricated, disposed in transverse bands close-set against each other; in other cases this covering does not descend on the sides, where it is replaced by scales. Other species have the upper and lateral parts of the trunk furnished with small, nearly oval, ridged scales, which are distributed in longitudinal series and transverse bands, their interspaces being filled with granules which are generally very fine. Above, the limbs are clothed with rhomboidal or lozenge-shaped scales, which are carinate and imbricated; and the carinate
of those scales on the thighs and legs are developed and prolonged into points to such a degree that these parts of the body are in truth bristled with spines. The belly is defended by a kind of plastron analogous to that of the crocodiles, that is to say, it is formed of a great number of quadrilateral, flat, united plates, disposed in longitudinal bands and transverse rows. The tail is surrounded by verticals of great rhomboidal scales, which, most frequently, are very spiny.

M.M. Duméril and Bibron further remark that Merrem has preferred the generic appellation here given to Cordylus, but which had previously been employed by Klein, Gronovius, Cuvier, Fittinger, and some others—arbitrarily, however, for the word Cordylus (Cordylus) was used by Aristotle not to designate a species of Zonurus, but a larva of a Urodèle Batrachian, probably that of Triton viviparous.

M.M. Duméril and Bibron, taking the arrangement of the scales for their basis, follow Dr. Smith in dividing the Zonuri into three groups, subgenera of Smith.

1st Group.
(Cordylus.)

Character of the Group.—A small fold of skin hardly perceptible in front of each shoulder. Skin of the sides of the neck hidden by spiny scales, more or less strong, which bristle its surface. Cervical and dorsal regions covered with quadrilateral scales. Scales of the sides resembling those of the back: a furrow allure along the lower region of each side.

Example. Zonurus griseus, Dum. and Bibr. Three varieties:
1. Yellowish on the head and upper part of the limbs, orange on the neck, back, sides, and tail. Lower parts white.
2. Black above; below white, washed with black.
3. Brown, more or less dark above, sometimes inclining to yellow, and nearly always on the medio-longitudinal line of the back a yellow stripe bordered on each side with small quadrilateral black spots. Under part of the body whitish.

Localities.—Cape of Good Hope, Senegal.

Zonurus griseus.

Species with the lower eyelid transparent.
Example. Zonurus polyzoanus, Dum. et Bibr. (Cordylus polyzoanus, Dum. et Bibr.)

Character. —Skin of the sides of the neck folded and covered by granules. Cervical and dorsal regions furnished with subimbricated scales, forming close transverse rows. Lateral parts of the trunk covered with granules.

3rd Group.
(Pseudoordylus, Smith.)

Character.—In front of each shoulder a very small fold descending to the middle of the anterior border of the breast. Skin of the sides of the neck forming parallel lines, and composed with granules. Cervical and dorsal regions furnished with suboval ridged scales, forming quadrilateral series, separated by rows of granules. Scales of the sides similar to those of the back. No fold along the lower part of the sides.

Example. Zonurus microlepidotus, Gray; Cordylus (Pseudoordylus) montanus, Smith. Colour. —Brown or or less deep above, inclining more or less to black. Upper parts and sides of the neck, trunk, and tail transverse orange, yellowish, or greyish bands, with white whiten when the animal is kept in alcohol. Under part of the head black, and the other under parts pale yellowish orange.

Localities.—Cape of Good Hope. Sierra Leone.

Zonurus in the arrangement of M.M. Duméril and Bibron is immediately succeeded by Tribolonota, Dum. and Bibr.

ZUOCARPES, the name given to certain organic bodies which have been variously classified by botanists and zoologists as animals or plants, and have been described as species of the characters of each. By a reference to the work of Ebrell on Animale, and to the 'Speculum Algarum' of St. James, Hooker's 'British Flora', &c., it has been found that the same genera which the one author describes as animals, the other classifies as plants. We shall not here enter into an examination of the opinions which have led to the classification of these bodies as either as animals or plants, as all naturalists are agreed to the principal facts of the existence of these genera. They are all agreed that these belong to a part of the organic kingdom of nature in which there is the greatest difficulty in seizing facts which, under ordinary detection, could not once determine their position in the animal or vegetable scale. Definitions which are so easily capriciously higher up the scale are of no use here, and it is only accurate analysis, and comparison of the structure with the functions of these organisms, that an approach to a correct classification can be made. The body to which the term Zoucarpes has been applied is placed by us in the natural order Alge. Of the higher groups of algae we have spoken under Sea-Weeds and Water-Plants, but it is in the lower forms more particularly the Zoucarpes occur. These lower groups form the division Gloiocladiaceae of Harvey and the Dizotomaceae of Brodmann. Most of the plants belonging to these divisions appear the form of slime on the surface of stones, rocks, walls, or of scums, froths, &c., on water.

The Gloiocladiaceae consist of plants with numerous submerged, invested, and definite gelatinous, forming globule or filiform fronds. This division include the Chaetocline of Bory St. Vincent, whose general account of these formations is quoted by Lindley in his remarks on the natural order Alge. He says the gelatine or the slime in which the plants are invested resembles a layer of albumen spread with a brush; it exfoliates in drying, at last becomes visible by the manner in which it colour green or deep brown. One might call it a primordial creation waiting to be organized, and then assuming the form and structure according to the nature of the corpuscle which penetrates it or develops among it. It may further be said to be the origin of two very distinct existences: one certainly animal, the other purely vegetable. The matter, lying among amorphous mucous capsules, consists in its simplest nature of a yellowish or brown albumen, so producing more complex states of organization. Sometimes the mucous, which acts as the basis or matrix of the corpuscles when it is found in water, which is the favourite medium for its development, elongate, thickened, and finally forms masses of some inches in extent, float and fix themselves to aquatic plants. These masses are at first like the spawn of fish, but they soon change.
colour and become green, in consequence of the formation of interior vegetable corpuscles. Often however they assume a marl or ferrugineous appearance; and in this state they are examined under the microscope, they will be found completely filled with the animules called Na-vicularia, Lunulae, and Stylaria, assembled in such dense crowds as to be incapable of swimming. In this state the animules are inert. Are they developed here, or have they found their way to such a nidus, and have they hindered the development of the green corpuscles? Is the mucous in which they lie the same to them as the albuminous substance in which the eggs of many aquatic animals are fertilized? At present we have no means of answering these questions."

The following are the characters of the genera of this division, Gloiocladacae:—

Tribe I. Protncoccus. The plants in this tribe are filiform or globose, composed of articulated, branched filaments, invested with gelatinite. The fructification, so far as it is known, consists of capsules on the ultimate ramules. They are found under the influence of both salt and fresh water.

* Filiform.

Mesogloia. The axis is gelatinous; the periphery composed of branched subchitinous filaments.

Biatrochopseum. The filaments are hyaline, longitudinally striated, set with diamit whorls of moniliform ramuli.

Draparnaldia. The filaments hyaline, emitting scattered penicils of coloured ramuli.

Coryneophora. The frond camosu-coriacous, hollow, formed of filaments issuing from a central point.

Myriogona. The frond minute, gelatinous, parasitical, composed of single filaments, fixed at their base to a thin expansion.

Tribe II. Rivulariae.—The plants are more or less globose (never filiform), camose, composed of continuous filaments, united within. To this tribe belongs but one genus, Rivularia.

Tribe III. Nostocinae.—The plants more or less globose, gelatinous or carose, including granules scattered through the mass or arranged in moniliform series.

Protncoccus. The globules aggregated, naked, filled with granules, seated on a hyaline jelly.

Hemturococcus. Minute gelatinous fronds, aggregated into a frutulous crust, and including scattered granules.

Palinna. A polymorphous gelatinite, filled with distinct globules, somewhat united within.

Echinula. Minute gelatinous fronds, filled with elliptical corpuscles, radiating from a centre.

Nostoc. A gelatinous polymorphous frond, filled with crop moniliform filaments.

The species of Mesogloia are marine plants. They are of a purple, rose-red, or green colour. The M. Huberti is found on the coast of Devonshire. Mrs. Griffiths says of this plant—"The structure is very remarkable: the frond appears to be made up of tufts of fibres, radiating from a central point, each tuft, when separated in water, is united under a glass, resembling a double Aster or Sea-Anemone. In the centre of the petal-like fibres are masses of purplish grains."

The species of Biatrachopseum and Draparnaldia are found in fresh-water streams and wells. They are not numerous. The latter genus was named after J. P. R. Draparnaud, a French botanist, who has paid much attention to the study of the Algae. The Chaeophyceae are green, chlorophyllous, filamentous, round, jell-like looking masses, and are found attached to pieces of stick and other objects in boggy pools, streams, and rivulets.

Coryneophora and Myriogona are small genera, and are found where the sea washes, on the pebbles of the shore, or on rocks and on sea-plants. The species of Coryneophora are numerous, and are found both in the sea and in fresh water. The crust of these plants is sometimes so closely attached to the rock on which it grows, so scarcely to be distinguished from it except by its colour. They are mostly of a red colour. The commonest species, the P. nivaeus. This little plant has gained a large share of attention on account of its being supposed at one time to be the cause of red snow. Now however the animal kingdom has put in a claim for a share in the production of this phenomenon. [Snow, Read.] Most of the species of Haeckelia, and Bivularia, a family of polygastic animules. Many of them have certainly the power of locomotion during the whole period of their existence, and not like some of the Zoo-carpus, which only move about at the commencement of their organic life. The species of Nostoc are found on rocks, both in sea and fresh water. Most of them are gelatinous, of a yellow or green colour, or transparent, and shrink almost to nothing in drying.

The division Diatomaceae consists of granules of various forms, plane or compressed, more or less transparent, rigid, often fragile, arranged in a lengthened or circular mass, which are free, packed, or imbedded in a mucous mass, and at length separating into distinct segments.

Of the two divisions, this is certainly the most anomalous with regard to its relation to the animal or vegetable kingdom. Agardh in the British state of the question of animules, which he referred here have as much relation to the mineral as to the animal or vegetable kingdom. He says that some of his Diatoms are nothing more than vegetable crystals, bounded by right lines and collected into a crystalloid form, and having a colour derived from minerals than that the individuals have the power of again separating. The following is the arrangement of the British genera of this family from Hooker's British Flora:—

Tribe I. Desmidiae.—Filaments cylindrical or angular, at length separating into segments, which are called frustula.

Melosira. Segments forming simple pseudo-articulated filaments, constructed at the articulations, fragile, and easily separating. 

Desmidium. Segments forming simple angular pseudo-articulated filaments, transparent at the crenated angles, at length separating.

Tribe II. Fragilariae.—The filaments plane, extremely fragile, composed of rectilinear segments, united together and forming a frustule.

Fragillaria. Segments forming pseudo-articulated, densely striated, fragile filaments, separating at the stria.

Achnanthes. Frond stipitate, standard-shaped, composed of a few segments, which at length separate and form a frustula.

Diatoma. Segments forming pseudo-articulated plane filaments, at length separating and cohering at their angles. 

* Frustula. Segments linear, free or imbedded in a shapeless mass, solitary or binate.

Tribe III. Siggilariae.—Segments plane, wedge-shaped.

Siggilia. Segments wedge-shaped, separate, stellate, not united into plane laminate.

Liencnophora. Segments wedge-shaped, fimbriated, stipitate.

Meridion. Segments wedge-shaped, in plane sessile circles or segments of circles.

Tribe IV. Cymbellacea.—Segments elliptical.

Gonyphonema. Segments subgenuine, terminating a very slender simple stalk, linear or wedge-shaped.

Homocladia. Segments arranged in numerous, binate, distant, parallel series, within a tubular frond.

Berkleya. Segments in longitudinal series, within simple mucous filaments, which are free at the extremity, but united below into a roundish gelatinous mass. 

Micromega. Segments arranged in longitudinal series within a cartilaginous or gelatinous frond.

Scizozonium. Segments in longitudinal series, and included in a simple or branched, filiform, mucous, membranaceous frond.

Cymbella. Segments elliptical, binate, free or imbedded in a mucous mass.

Such are the definitions of these genera, as given by
botanists. With a somewhat different technology, the same genus with the same names are described by zoologists. Thus of the above genera, Ehrenberg, in his "Insuffusions-thierchen," claims the genera Frustulia, Achnanthes, Fragilarién, Schizonema, Desmidium, Gomphonema, Meridion, and Micromega, besides many species from other genera.

The minute bodies belonging to this division of organized nature are found wherever water exists in any quantity. The pebbles on the sea-shore, the rocks on the coast, and various species of algae and plants of marine growths, together with the shells, and rocks, and various kinds of trees, and plants, and human beings, and animals, and fish, and a host of such other things, and with them, and they can only be detected by the naked eye when collected together in such quantities as to alter the colour or apparent consistence of the substance in which they are found. They are not however at all sea-water, nor are they found in fresh water, rivers, and brooks, boggy pools, ponds of stagnant water, and mineral-springs, and many of them will make their appearance in solutions of salts and infusions set aside for only a few days. The forms of the segments or frustule are various; sometimes they are quite flat and angular, at other times they are more or less globose. In many instances these segments consist of silice, and when regarded as animals, this part of the body is called its skeleton. It is on account of their siliceous character that many of the species of these animals have been lost in a fossil state, and already fossil species have been described that have not yet been determined to exist in a recent state. Although exceedingly minute, they sometimes collect in large quantities, and give a nodular character to objects on which they are deposited when dried. In "The Proceedings of the Linnean Society" for December, 1840, Dr. Lankester traced the apparently whitewashed appearance of the stones in the bed of the river Annan in Dumfriesshire, to the existence of these minute Diatoms. The species described in this instance has been described by Ehrenberg as the Synedra Ulna, and by Greville as the Dintom truncatum.

These little bodies were parasitic on a Convera that covered all the stones, and it was only when the river fell during the summer that the white appearance was observed on the stones. Many of the marine species so entirely cover the plants to which they are attached, as to give them a different appearance altogether. The segments are mostly transparent; they are however sometimes green, brown, yellow, or rose-colour. They are frequently marked in the inside with globules, granules, or strie, and it is to these that Ehrenberg has assigned the functions of stomachs, ovaries, &c., and on the ground of this structure, together with their power of locomotion, has referred them to the class of animals. The history however of these organisms has not yet been sufficiently worked out to enable any one with certainty to refer them either to one division of the organic kingdom or the other. In the mean time an important field of inquiry is open to the naturalist, who desires to pursue this subject, and who may be interested in the investigation of materials and the philosophical application of data.

Let any competent person look not only at the mass of existing species, but at those which are extinct, known only by their fossil remains, that have been noticed since the last acquisition, but which has hitherto passed without a considerable accession—and he will be pardoned for thinking that it is somewhat hard to draw conclusions without having the whole of the premises before us.

Alston's method was founded on a division of these which may be arranged, first, with reference to each group (sæc æve or sæc ëlæ) of the des plantae, according to a species, for example, which has pectoral mammals, apes, and elephants; and animals which have abdominal mammals—dogs and cats.

To the accuracy of Aristotle's descriptions those who are qualified by an acquaintance with the subject and the language will bear testimony; but it must be owned that some of those who have attempted the task have been very mean or have not perceived or have not been aware of the science of Greek, and none of the science on which its invaluable work depends. His talent for observation and generalization was of the highest order; and never did man more skilfully employ the ample means which the liberality of his royal patron placed at his disposal.

Of Alcian (Aléian Claudius) it may be sufficient to say here that he seems to have kept a sort of patent receptacle for any information relative to such knowledge as he could collect, which he put together without knowledge of the preceding or contemporaneous investigations and entertainments of Pliny, proue he was to record tale, as an author of a very different capacity; but the ideas that he gave to society was filled from the art of Aristotle, on whom he drew largely for his zoological.
descriptions generally. In the almost equally amusing pages of Aristotle will be found a scattered but copious collection of facts relative to imimals, stated apparently more with a view to the pleasures of the table, the leading subject of the book, than to the advancement of natural history.

In the interval which ensued between the age of the ancients and the revival of letters much zoological as well as other scientific knowledge seems to have been preserved among the Arabs and in the East generally, where it became, however, highly charged with fable, as in the account of the Roa; magnitude, which is a principal element in the more important notions of the sublime, being the prevailing exaggeration.

Albertus Magnus appears to have been the first European writer of note claiming the zoologist's attention, after the silence of the dark ages; and in his Historia Animalium, various tracts of access to antient authorities no longer exist.

Belon had deeply studied Aristotle; and the works of the French traveller on the natural history of birds and fishes not only contain much valuable information, but an attempt at classification. [Birds; Mammalogy; Reptiles.]

The brilliant style of Buffon fixed the attention of the civilized world upon the subject which his eloquence at once rendered captivating. A more severe writer might have done greater things for natural history as a science, but Buffon at once secured a willing audience and made all Europe his class. To him above all others may be conceded the merit of making the subject decidedly popular and for ever. The way was thus prepared for Linnaeus.

In the last edition of the Systema Naturae, revised by its great author, the Animal Kingdom is thus arranged:—

The Natural Division of the animal kingdom is indicated by the terms in each family; while philosophical disquisitions may, without hesitation, be placed next after Aristotle himself. [Birds; Mammalogy; Reptiles.]

V. Insects.
Sphena, antennæ thickest in the middle. Phalaen. antennæ thickest internally.

VI. Hydroptera.

Libella, tail with nippers; mouth multi-mucilaginous; wings extended. Ephemerello, tail with two bifles. 1: mouth toothless; wings erect. Myrmeleon, tail with nippers; mouth bit dentate; wings deflected. Pappus, tail simple, mouth bit dentate, wings deflected. Penna, tail chelate, mouth rostrated, wings incumbent. Regina, tail with one thread (filo); mouth bit dentate, wings deflected.

V. Hymenoptera.

Cympis, sting (aculeus) spiral! Trichobiris, sting serrate! Bivale. Sirex, sting serrated under the terminal spine of the abdomen. Ichneumon, sting exerted! Triple. Sphe, sting punctorial; wings flat; mouth tongues. Ophiops, sting punctorial; abdomen vailated (formeius). Vespa, sting punctorial; superior wings plicated. Pseus, sting punctorial; superior wings plicated. Pernio, sting obsolete; no wings on the neuters. Muscile, sting punctorial; no wings on the neuters.

VI. Diptera.

Ectcta, mouth closed; no mouth. Tipula, mouth slit lateral; four palps. Musca, mouth toothless with a proboscis. Tabanus, mouth with a proboscis and connect. teeth. Culex, mouth with a siphoniform process; mouth with a proboscis. Empusa, mouth with an inflected maxillose; the mouth with a stinger. Aulius, mouth with a subulate projecting rostrum. Babylia, mouth with a projecting setaceous rostrum. Hippob., mouth with a submutant, very short subrostrum; subrostrum 0.

VII. Apitera.

* Six feet. Head distinct from the thorax. Lepisma, tail with exerted bristles. Pollina, tail bifid, inflected, salatorial. Termea, mouth with a mucilaginous. Pediculus, mouth with a sting; aculeus of being the ends. Mouth with an inflected maxillose with a sting; feet salatorial.

** Feet 8—14. Head and Thorax united.

Acarus, eyes 2, feet 8, palps Palangia, eyes 8, feet 8. palps. Chanore, eyes 8, feet 10; first pair chelate. Monoculus, eyes 2, feet 14.

*** Feet multitudinous. Head distinct from the thorax. Scolopendra, body linear. Julis, body cylindrical. It is possible to feel that the specimen without being struck with the comprehensive views of the author, who the imperfect light which existed at the time is considered. Reaumur, Swammerdam, Moutet, Goedart, De Bounet, and Lyonnard indeed had described the Julis; but the Systeme Naturae was published: but many of the leading characters of insect-organization were still involved in darkness. One great error will be manifested to all the classification of the Crustacea among the invertebrates. The most curious observation must have satisfied Linnaeus that the Crustacea breathed by means of gills, and that therefore they could not be placed under the same category with animals whose respiration was carried on by Spiracles: Pani Later. It is not less interesting to consider the terrestrial habits of the Land and Water Crabs [Brugus; Gecarcinus; Pagurus] might have weighed with him, in the absence of any definite information when it was written. The most observant and enlightened labourers in this department, that one that will seem to be a work is at the disposition of the genus Cancer, Scylla. The most novel observation must have satisfied Linnaeus that the Cancer breathed by means of gills, and that therefore they could not be placed under the same category with animals whose respiration was carried on by Spiracles: Pani Later.

Ceratothorax, thorax mucronate-callosus at the sides. Lepitoca, maxillae attenuated at the apex; thorax rather smooth. Centuaria, clavulae existent; abdomen plicato-papillate at the sides. Estelar, point (mucro) of the breast resilient from a pore of the abdomen. Cecidela, jaws exerted, toothed; eyes rather prominent. Buprestis, head retracted within the thorax. Dytiscus, posterior feet ciliated and formed for swimming (natail). Carabus, thorax obtus- date, truncated posteriorly. Necydalis, elytra dimidiate; wings asked. Forficula, elytra dimidiate; wings covered; tail with nippers (forcipata).

II. Hemiptera.

Blatta, mouth maxillate; wings coriaceous, flat; feet ciliordial. Manis, mouth maxillate; anterior feet serrated; claw simple. Gryllus, mouth maxillate; posterior feet salatorial. Polgara, rostrum inflected; forehead (frons) produced, empty (inanis) anthera capitate. Crcoa, rostrum inflected; posterior feet salatorial. Notopara, rostrum inflected; posterior feet natalior (ciliated). Neta, rostrum inflected; anterior feet cheliiform. Cinxus, rostrum inflected; feet ciliatorial. Aphoe, rostrum inflected; abdomen two-horned. Cereus, rostrum pectoral; feet posterior; salatorial. Coccus, rostrum inflected; abdomen bristly behind in the males. Thripa, rostrum obsolete; wings incumbent on the reflexible abdomen.

III. Lepidoptera.

Papilio, antennæ thickest externally; wings erect.

Upper cruscatus with a straight suture Coleoptera 1. wings semicruscatus, incumbent Hemiptera 2. brumus with brumus Lepidoptera 3. membranaceous, anterior Hemiptera 4. Wings 2. Balances (Halteres) in lieu of the posterior wings. Diptera 6. Wings 0. i.e. the body without wings and elytra. Apera 7.

** Antennæ elavate, thickened externally. Scorabacus, antennæ with a fissile clava; anterior tibial dentate. Lucanus, antennæ with a compressed clava, the widest side fissile. Derrnest, antennæ with a perforate clava; a second salt, the scarcely marginate thorax. Hister, antennæ with a solid clava; head retrac- tile within the thorax. Bygrhus, antennæ with a solid ovate clava. Gyrius, antennæ rather rigid; eyes four. Astterius, head posteriorly attened. Caracolus, antennæ under the horns. Splinthus, thorax and elytra mar- ginate. Cochicetis, antennæ with an obtuse clava; palps with a truncated clava.

** Antennæ Riformis.

Bruchius, antennæ filiform, thickest externally. Cassida, body ovate; elytra marginate; head covered with a shield. Plistus, thorax receiving the head; antennæ with the last joint the longest. Chrysomelya, head ovate, immarginate. Hypsa, antennæ extended (porreeta), approximate, fusiform. Metacara, antennæ subrostrate. Thalia, antennæ dilated. Tenebris, thorax marginate; head exerted; body oblong. Lampyris, elytra flexible; shield of the thorax overha- damping and receivng the head. Mordella, laminae at the base of the abdomen; head infacted. Staphylus, elytra divided into two parts (dubia) covering the wing; two vesicles above the tail capable of being exerted.

*** Antennæ stecceous.

Ceranymbus, thorax mucronate-callosus at the sides. Lepitoca, elytra attemuated at the apex; thorax rather smooth. Centuaria, clavula eflexible; abdomen plicato-papillose at the sides. Estelar, point (mucro) of the breast resilient from a pore of the abdomen. Cecidela, jaws exerted, toothed; eyes rather prominent. Buprestis, head retracted within the thorax. Dytiscus, posterior feet ciliated and formed for swimming (natail). Carabus, thorax obtuse- date, truncated posteriorly. Necydalis, elytra dimidiate; wings asked. Forficula, elytra dimidiate; wings covered; tail with nippers (forcipata).

II. Hemiptera.

Blatta, mouth maxillate; wings coriaceous, flat; feet ciliorial. Manis, mouth maxillate; anterior feet serrated; claw simple. Gryllus, mouth maxillate; posterior feet salatorial. Polgara, rostrum inflected; forehead (frons) produced, empty (inanis) anthera capitate. Crcoa, rostrum inflected; posterior feet salatorial. Notopara, rostrum inflected; posterior feet natalior (ciliated). Neta, rostrum inflected; anterior feet cheliiform. Cinxus, rostrum inflected; feet ciliatorial. Aphoe, rostrum inflected; abdomen two-horned. Cereus, rostrum pectoral; feet posterior; salatorial. Coccus, rostrum inflected; abdomen bristly behind in the males. Thripa, rostrum obsolete; wings incumbent on the reflexible abdomen.

III. Lepidoptera.

Papilio, antennæ thickest externally; wings erect.

ZOO 808

ZOO
sections, became the load-star of zoologists. The Anatomie Compote, the Osteumossil, and, finally, the Régle of Animals, were the results of his acute and comprehensive demonstrations. In his hands Comparative Anatomy be

took a new form among the dynamics of natural history, and by its aid he rebuilt the extinct fossil forms that before his time lay scattered over the face of our earth in wild and apparently inextricable disorder.

It is not therefore surprising that Mr. W. S. Macleay thus writes:—"As to new views or principles in natural history, this mode of studying the variation of structure in different animals, in preference to classing them according to an arbitrary division of organs, is perhaps the only one to which I can justly lay full claim. It is possible indeed that Hermann, in his very remarkable work entitled Tabulae Anatomiae Animalium prior to this period, may have intended to keep some such principle as this in view; but, as with him, unfortunately, the slightest analogy constituted an affinity, we may understand how he found it impossible to trace the mode in which structures vary, as much more so to apply the maxim of arrangement. On a cursory glance at the principles of arrangement laid down by Aristotle at the commencement of his Historia Animalium, he may also be supposed by some to have understood this doctrine of variation in animal structure; but it is easy to show, that although this extraordinary man understood it to a certain degree, he confined himself in the passage in question to the division of organs,—a course of reasoning that led him quite away from the conclusions he would indubitably have arrived at, had he followed the variation of general structure. Still I shall not be surprised if the originality of even this principle be some day disputed with me; for when the question was asked, Is there anything more certain than that the earth has been inhabited in former ages, and that man has been formed on some principle of arrangement, the answer was, It hath been already of old time which was before us. And certain it is, that the doctrines of quinary distribution, of the circular progression of a series of affinities, and of analogies, as distinct from affinities, have all been in some measure advanced by analogy. The reason being, that some of the first great attempts that have been made in the construction of the universe given to it from the days of Plato and Cicero; that Linnaus, Pallus, and Desfontaines have mentioned certain analogies in nature as distinct from affinities; and that one of the most distinguished zoologists of the present age, and a foreign mem-

ber of this Society, Professor Gottlieb Fischer, of Moscow, has stated the progression of certain series of affinity being in circles. I can safely say however, that as I arrived at a knowledge of Lamarck's theory of gradual evolution or development, a theory to which the experience of every succeeding day becomes more and more opposed. About this period, almost contemporaneously with a similar movement in botany, some of the more imaginative and philosophic minds began to perceive analogies in organs and parts of the animal frame which previously had only been regarded under their distinct or individual elements. In general such knowledge of these generalizations of this nature which first made comparative anatomists acquainted with the bones of the cranium and the essential resemblances, or homologies, as they are termed, of the component elements of a vertebra under the names of caryons and the like, have been added to by our knowledge of these analogies in the animal individual, is too closely connected with similar researches after analogies and analogies in zoology to be omitted in the present sketch of the history of that science. Goethe, he founder of morphology, or the doctrine of organic analogies in plants, also made the first step in the advance-

ment of similar, or, as they have been termed, transcen
dential views, in the anatomy of animals. The poet's dis-
covery of the intermaxillary bones in man, the first fruits of this essentially synthetic mode of analysis, was so immediately followed by such similar brilliant ap-

creations of true analogies by his successors Oken and Geoffroy, and the disciples of their school, which have more than compensated for the less substantial results of the exuberant imaginations, which have too often had the effect of deterring the sober student of nature from digesting the words of authors from which valuable information s to be obtained.

Germany and the Netherlands have reason to be proud of the names of Illiger, Temminck, and Wagler. Of these M. Temminck continues to enlighten zoologists with his excellent works; whilst Professor Lichtenstein and Dr. Rüppell still pursue their praiseworthy course.

In our own country and time the Quinary System has been adopted by one of our most accomplished zoologists in his Horse Entomologica, An-

nulosa Javanica, his Remarks on the Comparative Ana-

1 Lecons d'Anatomie Comparée, vol. I.

4 Zoological Society, No. 1781.
for the naturaliste. 1. La moisissure produite par la cor-
ruption des matières animales; 2. L'origine des animaux
infusoraires par celle des matières végétales. Les bornes de
cet ouvrage ne permettent pas de développement plus
ample de cette idée qui présente une vérité à poursuivre."
Again, in page 184 in the following passage: "— Il ne
faut pas croire que la série des Mammifères soit à consi-
derer dans une direction droite comme une suite. J'ai
fait quelquefois voir qu'elle forme une galerie ou la
vuteur se trouve à un milieu, ayant les espèces d'animaux
de ces côte. C'est-à-dire, l'auteur s'imagine que chaque
série de la première division dont les doigts ou pieds ne
sont réunis par une membrane, traverser de l'figure
par les autres parties, la séparation, le cote, les espèces
qui, pieds ou pieds sont réunis par une membrane. Une représen-
tation des genres de Mammifères en cercles entourant le
centre ou est placé l'homme, et se touchant mutuellement,
suivant que les propriétés de différents animaux se sem-
blent sourt peu-t-être la plus conforme à la Nature.

Mr. W. S. MacLeay has brought to bear on his intricate
subject a comprehensive knowledge of natural history,
much learning, and the close astute reasoning of a mind of
indeed some of his. The system has been applied in this
country, by Mr. Vigors, to the Birds, and by Mr.
Bennett, to the Mammalia and fishes. With certain modi-
fications it has been applied, by Mr. Swainson, to theanimal
kingdom generally, who, in his arrangement in the several
volumes of the 'Cabinet Cyclopaedia' filled by him, has
however left out Man.

On the Continent the Quinny System has never found
favour, and it has now few if any followers in this country.
But it may fairly be said of it, that, like the system of
Linnæus, it has influenced more both in science and ama-
ties. We have heard it lamented by some, that a man of
judgment should, unconsciously perhaps, have employed his
powerful mind in a mode calculated to rivet the fetters
that Bacon had struck off; but these could hardly have been
avoided, as was the name, and with which Mr. MacLeay
constantly impresses on his readers that zoology is a science
which must always depend upon experience and observed
facts; and that the grand object of comparative anatomy
is the formation of such a collection of recorded facts of
comparison as will demonstrate the use of the various organs;
and, above all, may lead us to the better knowledge of the natural arrange-
ment of the animal kingdom.
The thought may be said that, like those
who treated the Bacsonian or inductive method with con-
tempt, and laughed and railed by turns at the author of the
'Novum Organum,' immediately after its publication,
not many had read his works through; and of those, few
had taken them.

That he was wrong in some of his notions may be true:
for instance, he has most ingeniously endeavoured to show
that the Cephalopod approximates to the Turtle (Testudo);
but Professor Owen has proved to us by dissection that the
Cuttlefish comes nearest to the Mynas and Lampree
among the Vertebrata.

It is not fair to make Mr. MacLeay answerable for the
vagaries of his followers, and the Procrustes-like violence
with which they occasionally force a form into what they
conceive a proper place merely because that vacant place
wants a form. If his injunction to inquire into the organi-
ization and habits, as a first and necessary step, had been
attended to, 'Cathetora' would never have been placed
among the Vertebrata (Vertébrés; Télaugolla), not the
case of an insect among the Mammalia (Théliodömes).
A striking feature in the zoological character of the pre-
ent period arises from the numerous monographs which
have appeared or are still forthcoming. It is by such
catalogues and collections of materials that the path of the sys-
tematist is especially enlightened.

In America Wilson's delightful book and the magni-
ificent work of Audubon have opened up the complete
natural history of the birds of their country; nor must the
abundant work of Nuttall be forgotten.

In Italy Poli had familiarized us with the organization
of the Mollusca in the Sicilian seas; Delle Chiave and Phi-
lipe had followed him, and Madame Power has settled
the subject by the discovery of the shell of the
Pap. Nautilus. The Prince of Canino and Musignano, who had already so ably supplied what was
wanting in Wilson's American work, has left nothing to be
wished in his excellent Fauna Italice.

England had produced the prominent names of Wil-
lugby, Pennant, Latham, White, Leach, Berck, Mar-
tag, Selby, Gray, Swainson, Stephens, and Cuvier; but a
powerful stimulus to the Zoological Society of London,* in
the establishment of which Sir Stamford Raffles had the principal share. To the
taste for zoology thus diffused may in a great measure
be attributed the ready acceptance which the great
Hand-Book of Natural History received, and the more
slowly found or are finding, and the well-merited praise
which has enabled Mr. Gould to publish his mag-
ificent works. 'The Birds of the Himalaya Moun-
tains, The Birds of Europe,' the monographs on the
Hampshire Fishes, and the Reptiles, and, though
least, not least, 'The Birds of Australia,' have all been
worthy to the manner in which it is that science has
been advanced. We are assured that the results of Belcher's voyage and James Ross's southern
expedition.

In France the spread of zoological knowledge has become
most extensive; and all Europe has been deriving sat-
isfaction from the publication of admirable hand-books,
treated Manuals of the French zoologists. The Mammals
and Ornithology of Lémel, the Manuel de l'Homme of
Nouelle des Mollusques de Rang, the Comparative
the Zoology and Actinologie of De Blainville, and a
number of other works have been published, which have
been of important use to every one engaged in the study.
In the Suites à Buffon, the Reptiles have been most
elaborately worked out and illustrated by Duméril and Robin of
the Zoological Society of Milne Edwards. To crown all, the
Osteologie of De Blainville shows in the course of publi-
cation, a work which will confer honour on the nation
al school of zoology.

But we have been far from idle in England while fol-
lowing the steps of Cuvier in the compilation of plas-
tology. Conybeare, De la Beche, and Buckland have
broke ground in the search for fossil animal forms; and
although we cannot claim Agassiz as a countryman,
we have had the satisfaction of incurring in the publica-
tion of his great work on fossil fishes, which has
riched the fossil catalogue beyond hope in almost every
class of Vertebrata, and, among these, the grand gen-
erous additions, Mylodon, Glyptodon, Téxodon, have
been enormous reptiles, and, lastly, the gigantic Icthy-
Newfoundland and, eminently successful. Professor Owen has shown that the macro-structure
brought to bear upon the largest as well as the smallest
creatures being.

The articles relative to zoology in this work may be
found by reference to the following index:—

Kingdom, Animalia.
Sub-Kingdom, Vertebrata.
Class, Mammalia.

Mammalogy.
Sub-order, Placentalia.
Order, BIVANA.

Albinous, Man. Skeletou.
Order, Quadrumana.

* In the article Wor-Wor the words 'Arab Pheasant' are errone-
ously printed for 'Arab Phasianus.' But one living Arab Phasianus has
we know, has ever reached England.

+ BAYO. The height of the numerous genus Deinos, has, like the
height of the Cuvierian, shrunk before the severity of competition.
With this great animal, a great creature, and a shell which, so to
say, was assigned to the largest known species, Deinos pisces, has led to
the passionate discussion, which has been involved in the name.
The most curious part of the present animal is the comparative shortness of the thoracic segments, which is a fact of
which, nearly half of the shell is formed. Professor Owen has also
made out five species, none of which is small. The strange* mem-
brane of the back of the neck has led Professor Owen to the
country * of Deivos inhabited by scraping up the coat of the
* Merina for their food.

CLASS ZOOPHYTA. Body surrounded anteriorly with a simple circle of pinnated tentacula (generally eight in number); ovaries internal.

Some of the animals are single, others aggregated; but in general they are organically united in a common living mass, as the buds of a [dicotyledonous] tree are united to the trunk.

Family 1. Tubipora: including the genera Cuscuctaria, Telesto, Cornularia, Clavularia, Tubipora. [TUBIPORA.]

Family 2. Corallina: including the genera Corallium, Lophia, Gorgonias, Eunice, Pachinia, Plexaura, Muricea, Primnoe, Antipathes, Cirripathes. [POLYPARI A CORRITICA.]

Family 3. Pennatulacea: including the genera Umbellaria, Virgularia, Pavonaria, Pennatula, Veretillum, Re-

These families appear for the most part natural and well defined; because the structure of the Polypi, the manner of their union, the composition of the polypiferous masses, and their free or attached habit of existence have all been compared. One general mass of classification is referred to these volumes, that of M. De Blainville, who, in his Actinologic, it appears well fitted to introduce the student to a contemplation of the innumerable forms comprehended under the term Zoophytes; but it is evidently capable of improvement hereafter, when the ever increasing researches of microscopists and anatomists have made us more fully and exactly acquainted with the true relations of the internal organization of the Polypi of the several families to the structure of the higher groups of the animal world.

In the point of view the reader will And much advantage from consulting the Summary given by Dr. John- ston, in his work on British Zoophytes, 1836; the detailed examinations of particular groups by Milne Edwards (An- nales des Nat. d. parasites, parisiens); and the efforts for classification by Dr. Farre (On the Phyletic Position of the Zoophytes of the Royal Society (1837). As Blainville's classification includes the Actinopoda as a part of the Zoophyta, we have given under that head a copy of his general Tab. as an Index to the whole subject [ZOOPHYTA].

ZOTITICA. [VARITANIAN, p. 133.]

ZORASTER, or ZERDUSHT, the founder of the religious system of the Parsees, was born about 586 B.C., at Urmi, a town of Azerbaijan, in the reign of Lohaspas, the father of Gushaspas (history of the Persians). His parents were in a humble condition, although of a noble family, and some of the Eastern authorities trace the lineage of his father, Purushasp, to Feridoon. Daghsis (Anqetis) wrote Dogola, the mother of Zoraster, is also said to have been one of the earliest of the women who sold him to oblige his father; but it is reported to have been so spotless as to attract the favor of the Deity, who foretold to her the greatness of Zoraster, while yet in the womb, through the medium of magic dreams. Zoraster was said to be born in the month of Shahrvar. The birth of the Persian prophet was attended with many miraculous circumstances calculated to make the persons who saw it adopt and spread the belief in the divine mission of the new-born infant. Many of these miracles have found their way into classical writers, and many mentions that Zor- aster laughed on the day on which he was born, and that his brain palpitated so violently as to repel the hand when placed on it. (Hist. Nat., vi., c. 16; H. Lord's Account of the Modern Parsees in India, c. 3.) Miracles of this kind were always made to precede the life of a remarkable man, and they serve to show the high influence which Zoraster obtained throughout life, and the respect which posterity paid to him in this respect. The years of Zoraster's childhood quietly passed in his native town—although his historical life in adorning them with the most extravagant accounts of his exploits when a child. However, he must have soon turned his attention to the study of nature, as it is probable that he passed twenty years in the depths of the mountain Elbroos (Plyni mentions this with a slight alteration, Hist. Nat., xi., c. 42) before he went to the court of Gushaspas, at which period he is said to have been only thirty years of age (Hycl., p. 580, on the authority of the Orientalists). His having secured himself from the society of men for a great number of years is a fact corroborated by many independent authorities. It was his retirement that the will of the Supreme Being was known to him, and as this portion of Zoraster's life—one upon which the Parsees rest most of the evidence of the truth of his divine mission, we shall relate it here.

Zoraster's journey to the mountain Elbroos is by Parsee authors invariably called the prophet's journey, heaven, where he received his instructions from the (e. g. the Zend-Avesta and the sacred fire). He says, "I went to Zerdusht-nama, and I saw the sun, and with his head covered by a veil, appre- before Zoraster, by the command of Ozmaid, said, 'Who art thou? What dost thou want?' Zer- answered, 'I seek only what is agreeable to Ozma And be pleased with me. O Thou, who are pure, show me the way of law.' These words pleased Behanam. 'Rise,' said, 'to go before God; there thou shalt receive the same thing.' Zoraster rose and followed Behanam, said, 'Shut thine eyes, and walk swiftly.' When Zor- opened his eyes, he saw the glory of heaven; then came to meet him, and with them he approached the person to whom he addressed his prayer. From this in- cluded, he undertook to spread the teachings of the following instructions: Ozmaid himself said: Latter, 'Teach the nations that my light is hidden; all that shines. Whenever you turn your face towards light, and you follow my command, Aryan days will be supplied, after the ruin; and he said: 'The people superior to light.' He then bade him to book Avesta with the injunction to declare it before Gushaspas Behanam, the Amashapendar presiding over the surrendered his office to Zoraster, and gave him his pow- as the king of Shahrvar, and add as follows: 'The kingdom of Khordad, and Amirs followed the example of the Zoroastrians and returned to the world to overthrow false doctrines which were upheld by magicians and brought misery upon mankind.

When beholding the glory of the author of the life of Zoraster, was evidently invented for the purpose of filling up the chasm which the twenty years of the life of Zoraster, would have left.

Zoraster first saw Gushaspas at Balkh, and he saw this province to become a reservoir of the powerful sect of the Parsees. The Zinat-al-Tawarikh states that Ahdar son of Gushaspas, was the first convert of Zoraster, that his father was persuaded by the eloquence of the Zoroastrians. Behanam, that Zoraster said had been revealed to him free to spread rapidly in the province of Azerbaijan (i.e. the fire). Guaspas introduced it into every part of it and nations, and ordered 12,000 cow-hides to be tanned for it. These parchments were deposited in a vault near a rock in Persia.

The appointed holy men for them; and it was commanded that the profane should keep at a distance from the sacred book (Matras). The powerful protection of the king enabled Zoraster to introduce his doctrine farther than the kingdom where he heard of his Chahans, and that at the second son of Gushaspas, was sent by him to be announced in order to propagate his religion. He did to gain proselytes in India, and succeeded in converting a learned Brahmin (Tehengrighatcheh, according to quetil. vol. i., c. 2. p. 70), who went back into his own country with a great number of priests. Temple of this order and erected in all parts of the end of the expense of Guaspas, whose zeal in imitating the Zend-Avesta not only on his own subjects, but as those of the neighbouring monarchs, at last engaged in a war with Arjasp, king of Turan. He entered into a treaty or alliance with the Persians and attacked all parties of the enemy, the expense of Guaspas, whose zeal in imitating the Zend-Avesta not only on his own subjects, but as those of the neighbouring monarchs, at last engaged in a war with Arjasp, king of Turan.

The whole history of Zoraster, when divided into
traneous matter, can be reduced to the following statement:—The ancient religion which Djamahid had established, can have become merely traditional as lost its influence over the nation; new sects had sprung up in every direction; Hindus and Chaldeans were endeavouring to introduce their own religion, when Zoroaster appeared. It is evident that the worship of elements had been extinguished by Zoroastrian Code, and earned his great reform in the adjacent empire; he therefore seems to have restored the religion of his ancestors to a state of greater purity and adapted it to the exigencies of a new age after the fall of the empire.

What we have said hitherto rests entirely on the authority of Eastern authors—it has no claim to historical accuracy; but it contains more than can be gathered from classical writers. The Life of Zoroaster, prefixed to Anquetil du Perron's Zendavesta, is compendium of all the earlier and more complete histories which have been invented about Zoroaster.

From the different dates assigned to Zoroaster by Greek and Latin authors, many modern authors were led to believe that there were no less than six men of that name; but this opinion has been satisfactorily refuted by Hyde, in his 'Veterum Persarum et Magorum Religionis Historia,' and lately by Pastoret, in his 'Zoroastre, Confucius, et Mahomet comparés.' For an ingenious endeavours to prove that there was only one Zoroaster, compare to Stanley's 'Historia Philosophica,' (Dublin, Sec. i., c. 2); and to Bryant's 'Analysis of Ancient Mythology,' vol. ii., p. 388, where almost all the passages that can be found in antient authors relating to Zoroaster are very considerably.

Again, there were writers who identified Zoroaster with Moses, among whom Huet is the most prominent (Demonstratio Evangelica, Prop. iv., c. 5); others again have supposed that Zoroaster was born in Palestine, or that he perished after a shorter period. He is considered by many as an ancient prophet and earned his substance by becoming a servant to a Jewish prophet (Hyde, p. 316). Abul-Faraj states this prophet to have been Eljah, Hyde thought he was Esdras, while Prideaux conjectures that Zoroaster had been servant to Ezekiel. It is even possible to identify the Zoroaster of Persarum, Aramath, and Zoroaster of the Zendavesta, but this would be rather vain and useless. There was only one Zoroaster or Zendusht, who lived in the time of Goustasp and effected a great reform.

The leading doctrines propagated by Zoroaster were the following:—He taught that God existed from all eternity, and was like infinity of time and space. There were two principles in the universe—good and evil; he one was termed Ormuzd, or the good principle, the other Ahura Mazda, or the evil principle. Each of these had the power of creation, but that over was exercised with opposite designs; and it was from their united action that an admixture of good and evil was found in every created thing. The angels of Ormuzd protected the human race, and the human race, which the infernal agents of Ariman—destroy. But the power of good alone, the great Ormuzd, was eternal, and must therefore ultimately prevail; light was the type of the good spirit, darkness of the evil spirit; and, as stated above, God said to Zoroaster, 'My light is concealed under all that shines.' Hence the despair of that prophet, when he performs his devotions in a simple, turns towards the sacred fire that burns upon its altar; and when in the open air, towards the sun, the obelisk of all lights, and by which God sheds his ivine influence over the whole and perpetuates the works of his creature. (Armanes.)

Zoroaster, we are told, was a great and good man; and the counteract of Porphyry, that Darius was so proud of having been initiated into the mysteries of the art by Zoroaster himself, that he ordered it to be incribed on his tomb. After the death of the religion he introduced was disturbed by a thousand sects; many reforms were introduced: but they gradually sank to a mere idolatrous worship of the fire and the sun; the worshippers were persecuted when dohomanians rulers had possessed themselves of Iran; but the refraction of the sects, the sawing of the elements, the seeing of the fire, and settled in Guzerat, where they are to this day, but greatly diminished in number.

Hyc. 'Veterum Persarum et Magorum Religionis Historia, Oxford, 1780; Anquetil du Perron, Zendavesta, Paris, 1771; Pastore, Zoroastre, Confucius, et Mahomet comparés; Malcolm's History of Persia; Bayle, Diction. Historique, has a long and curious article on Zoroaster.)

ZOSIMUS (Zosimos), a Greek historian of the time of Theodnius the younger (a.d. 408-450). He is described by Photius (Bibl. Cod., 98) as ευνούχος καὶ ἀτές φησινόνοχος; (comes et excedavatus fisci), and was perhaps a son of Zosimus, the prefect of Euporius, who is mentioned in the Chronicle of the Euporians. Zosimus was the author of a historical work still extant (τορογια οριστοιον), in six books, which 'appears to have been produced in the year a.d. 437,' (v. 27) mentions an occurrence which happened in that year. It is joint with the history of Augustus, and after having given in the first book a sketch of the history of the emperors down to the end of Diocletian's reign, a.d. 305, the author devotes the remaining five books to a more detailed history of the Roman empire down to the year a.d. 406, when Rome was besieged by Alaric a second time, and Attalus was declared emperor. Zosimus seems to have been pretty well acquainted with the earlier writers on Roman history. Photius says that his work was a mere compilation from the chronicle of Eunapius, who however is not mentioned by Zosimus. He also used the works of Deyxippus and Olympiodorus, from the latter of whom he has copied the history of the Persian wars. As Deyxippus did not examine the credibility of his source, his own work is however of no importance. It is possible that Zosimus might have access to the Greek text, with the translation of Leucius (though the translator's name is not mentioned) that of H. Stephens, Lyon, 1581, 410. In this edition Zosimus is printed with Herodian. Zosimus is also contained in Pr. Syenses, 'Romaneae Historiae Scriptores Graeci, Frankfurt, 1501, fol.: this was followed by two separate editions of Zosimus, the one by Ch. Olearius (Zelir, 1579, 8vo., reprinted at Aens, 1714, 8vo.), and the other by Thomas Smith (Oxford, 1614, 8vo.). The ordinary text of Zosimus is that of Reitmeier (Leipzig, 1784, 8vo., with a valuable introduction, notes, and commentary), and of Emmanuel Becker (Bonn, 1837, 8vo.). There is an English translation, under the title of 'The New History of Count Zosimus,' &c., London, 1684, 8vo.

ZOSIMUS, a native of Greece, succeeded Innocent I. as Bishop of Rome, a.d. 417, under the reign of Honorius, Emperor of the West. At that time Pelagius and his friend Celestius were disseminating in the west their peculiar doctrines about the merit of good works and the freedom of man from sin. [Peluagianism.] Zosimus appears at first to have been captivated by the eloquence of Celestius, who was a ready and subtle speaker, and to be zealous for pious works. But the tenets of Celestius were soon after condemned by the council of Carthage, a.d. 418, and Zosimus confirmed the sentence of heresy against the Pelagians. A dispute about jurisdiction between Pope Pelagius and the Bishop of Vienne, Zosimus supported the bishop of Arles, but the other bishops of Gaul did not submit to his decision. Zosimus encouraged appeals from the bishops to the see of Rome. His letters on the Gaulish and Pelagian controversy are preserved in Constant's 'Epistulae Romanorum Pontificum,' Zosimus died in December, 418. (Muratori, Annales d'Italia, and the Church Historians.)

ZOSTEROPS, the name given by Dr. Horfield and Mr. Vigers to a genus of Insessal or Perching Birds, Vol. XXVI.—5 M.
placed by Mr. Swainson in his subfamily Pardalinae or Tameera in his family Sylviidae.

Generic Character.—Bill rather stouter than in Sylviola, acutely conic, almost entire. Rictus smooth. Wings moderate, pointed; the first quill rather shorter than the three next. Tail as in Sylleridae. Feet strong. Tarsus longer than the middle toe; Lateral toes unequal. Eyes encircled with compact white feathers. (Sw.)

Geographical Distribution.—India, Africa, America, Australia.

Example.—Zosterops flavus (Sw.), Yellow White-Eye.

Mr. Swainson, in his Birds of Western Africa, observes that the species of this genus are all of small size, and nearly intermediate in their affinities between the Warblers and Titmice. He states his belief that only one species is found in the New World; the others, about twelve in number, being restricted to the warm latitudes of Asia, Africa, and Australia. One of these, Zosterops curvirostris, Sw. (Dicran chloronotus of the Paris Museum), has, he remarks, the bill nearly as much curved as some of the honey-suckers.

Mr. Swainson adds that the general plumage of all those liliethro discovered is green above and yellowish beneath; so that the species, otherwise well marked, possesses a strong mutual resemblance in the general cast of their colours. He thus describes Zosterops flavus:

Size of Zosterops doratus, an Australian species, but the bill, which is black, is larger. The upper plumage is of a bright greenish yellow, the under pure and bright yellow, uniform in all its parts. The quills and tail are blackish, edged with yellow: the snow-white ring round the eye is very conspicuous, and it is connected to the base of the bill by a deep black line; the tail, although divided, is even, and the bill and feet blackish. Total length 4 inches. (Sw.)

Locality.—General.

ZOUCH, RICHARD, an eminent English civilian, was born about 1500. He was educated on the free foundation of Winchester school; elected to New College, Oxford, in 1567, and chosen fellow in 1590. He took the degree of Bachelor of Civil Law in June, 1541, and was admitted at Doctors' Commons in January, 1548. In April, 1549, he commenced LL.D., and was appointed Regius Professor of Law at Oxford in 1623. He represented his native county as one of the delegates in the cause of Don Panteleon de Sta, brother of the Portuguese ambassador, who was tried and executed in 1553, for the murder of an English gentleman. At the Restoration he was reinstated as judge of the Admiralty, and nominated a commissioner for regulating the University. He died soon after at his apartments in Doctors' Commons, on the 1st of March, 1681.

11. 'The Jurisdiction of the Admiralty Court asserted against Sir Edward Coke's Article Admirallitas, in the 22nd chapter of his Jurisdiction of Courts,' London, 1663, 8vo.; a poem of 14 stanzas. 15, 16. 'Species questionum juris civilis,' Oxford, 1683, 4to, has been attributed to Zouch. (Biographia Britannica.)

ZOUCH, THOMAS, an English divine, was born near Durham in 1702; entered Lincoln's Inn, and was called to the Bar in 1726. He was a member of Emmanuel College, Cambridge, in 1757. In 1760 he was elected one of Lord Craven's scholarships. He was chosen fellow of his college, and appointed assistant tutor in 1763, the state of his health obliging him to leave the University in 1767. In 1770, he was made a Fellow of New College, Oxford, and appointed deputy-commissary of the archdeaconry of Romney, and in 1793 chaplain to the Master of the Rolls and rector of Selsey. At the death of his elder brother, Rev. Henry Zouch, a year or two before, he assumed the name of Sandal, where he continued to reside till his death. In 1797, he was called to the second prebend in the chapter of Durham. The see of Carlisle was offered to him in 1798, but he declined it on account of his advanced age.

He died on the 17th of December, 1827, at the age of 77. He was an elegant classical scholar, and possessed considerable acquirements in botany. Besides several occasional courses, he published 'An inquiry into the Prophetical Character of the Romans, as described in Daniel,' 2to., 1792, and 'An account of the Prophecies of the Old and New Testament,' 1804. He also published some biographical works:—1. 'Memoir of Sir Robert Southey, Bart.,' 1796, 8vo. 2. 'Memoirs of the Life of the Right Honourable D., Lord Durham,' 1808, 4to.; and an edition of 'Inns of Court Lives,' with additions. (Gentlemen's Magazine, Vol. xxxi. Annual Register, vol. vi.)

ZOUZ, GERARD, called sometimes Sowor and Sonor, was a German portrait-painter of great ability, who established himself in England, and was one of Ley's rivals for the reign of Charles II. He was born in Westphalia in 1637, but the year in which he came to England is not known. Bickardon, in his 'English School,' says he came to this country about the year 1654, and found an engagement suitable to his merit. 'His portraits of men,' he continues, 'are admirable, having in them a just, bold, and good colouring; but he did not always execute with a due regard to grace in women's faces; which is not so much due to his talent, as to the weakness of his brush, which was not firm enough to execute with perfect beauty, in which his country did not greatly abound.' What we are most indebted to him for is a portrait of Mr. Riley, Walpole says of Zouz:—'By all that have seen of his hand, it is said that he had a man of singular temper, and was much displeased at Ley's female portraits being preferred to his. He was slovenly in his dress, and he often opened his house-door in Catterick's Alley or Holborn by himself, and if he did not like the look of his visitor, he used to say that his master we
not at home. Walpole mentions several portraits by him, among them a fine head of Logan, the engraver, one of Sir F. Throckmorton, and an excellent one of a gentleman in a dappled gown, on the back of which is written the picture of the picture and frame: the picture 36, and the frame 16. His draperies were frequently of satin, in which he imitated the manner of Terburgh. He died in 1681, aged 44.

ZUCCHARELLI, or ZUCCHERELLI, FRANCESCO, a distinguished Italian landscape-painter, born at Pittigliano, near Florence, in 1702. He first studied drawing-painting, but he eventually decided upon following landscape-painting, in which his first instructor was Paolo Anesti, at Florence. He afterwards went to Rome and continued his studies with Monanni, and lastly with Pietro Nelli. Zuccarelli established himself at Venice, but he acquired in time, through Smith's prints, after his works, so great a reputation in England, that he was induced to visit this country in 1768, as his ambassador, and was so much; to satisfy the most sanguine expectations. At the institution of the Royal Academy in 1768 he was elected one of the members, and is accordingly one of those who are considered its founders. Several of his pictures have been engraved by Vizares. "The frames are painted by himself; and 'tis has been remarked," says Edwards, "that among the figures which he introduced in his landscapes, he frequently represented one with a gourd-bottle at his wrist, is often seen in Italy. This is said to have been done intentionally, as a sort of pun on his own name, Zucco being the Italian word for gourd.

In 1770 Zuccarelli painted a set of designs for tapestries, which were executed by the king's tapestry-weaver, Paul Saunders, for the Earl of Egremont's house in Piccadilly. He painted many creditable pictures in England, but they are generally very inferior to those he painted in Venice, and to which he was indebted for his reputation and the fortune he made in this country. His later works are cold in colouring, want harmony, and are artificial in their composition; there are some specimens at Hampton Court. Zuccarelli, however, in his time, reigned over the public taste in England; and the chief cause of Wilson's want of success was because he did not imitate him.
In 1773 he returned to Florence, and he gave up painting, having resolved to pass the remainder of his life in quiet retirement by the super, illusion however by the emperor of Austria of a monastery, on the security of which he had advanced money, deprived him of his property. This misfortune compelled him to assume the pencil, and he found sufficient employment from the English gentlemen who visited Florence, where he continued to paint until his death in 1788. He etched some plates after Andrea del Sarto.

(Lanzi, Storia Pictorica, etc.; Edwards, Anecdotes of Painting, etc.)

TADEO, and FEDERIGO, two celebrated Italian historical painters, were the sons of Ottaviano Zucaro, an obscure painter, and were born at S. Angelo in Vado; Taddeo in 1529. He studied first with Pompeo da Fano, and afterwards with Giacalone da Fiesole, and went early to Rome, where he remained alone for some time. When he arrived there, he found himself friendless and houseless, and he was forced to seek employment as a colour grinder, but in this way he added little to his means, and he was for some time comparatively destitute. He painted several pictures in the churches of Rome, among the ancient ruins, or under the porches of the modern palaces or churches; and after much perseverance he was at last compelled by excessive privation to return to his father's house, there to recruit his shattered constitution. During his absence Vasari, he had been living upon his youth: but during all this period he let pass no opportunity that occurred of improving himself in drawing. As soon as he had recovered his strength, he returned with renewed courage to Rome, and this time his exertions met with little success. He painted the portrait of Daniello da Parma, who had painted some years with Correggio and Parmigianino, and who took Taddeo with him to Alvito near Sora, where he was about to paint a chapel in that town. He painted the portrait of Queen Elizabeth, and that of Mary Queen of Scots, which is at Chawick, and which Vertue engraved. He painted a second portrait of Elizabeth in a sort of Persian dress, which is or was in the palace at Kennington, in Surrey. He was also engaged in illustrating a book of poems by Sir Richard Woburn, and painted a portrait of the poet, which was later in the Palazzo Lante: there is an engraving of it by Cornelius Cat; it is one of Federigo's best works.

Federigo painted likewise the portrait of Sir Nicholas Bacon at Woburn, and those of Charles Howard, earl of Nottingham, lord high admiral; and Elizabeth's first pastor, now at Hampton Court. Walpole had a portrait of Sir Francis Walsingham by him.

He died at Dresden, where he was soiled and feverish; he was soon forgiven and recalled by the pope, and he returned to Rome and finished the ceiling of the Pauln. At the end of 1585, after the accession of Sixtus V. to the papal chair, Zucaro was invited by Philip II. to Spain to paint the Escorial, with a salary of a thousand ducats. He arrived at Madrid in January, 1586, and he was occupied in the Escorial nearly three years, during which time he painted several works in oil and in fresco, some of which however were immediately afterwards removed or destroyed. In 1590 and 1591 he returned to Rome at the end of 1588. In 1595 he founded the Academy of St. Luke there, for which a charter had been granted by Gregory XIII., and it was confirmed by Sixtus V.; he was the first president. He wrote a book on the principles of painting, sculpture, and architecture, entitled L'idea di Pitori, Scultori, e Architetti, and printed it in 1603 at Turin, with a dedication to the Duke of Savoy. He published two other works at Bologna in 1592; one of which Taddeo had left unfinished. He died in 1603. He was a great master, had great ability as a painter: he was also sculptor, poet, and architect, and he is said to have owed his success chiefly to his general accomplishments and
the lake, from Zug to Arth in the canton of Schwyz has been recently completed, and the town of Zug paid 30,000 florins for its share of the expenses. Zug has a gymnasia for four professors, and an institution for female education directed by nuns.

The other towns of the canton are:—1. Baar, about three miles north of Zug, on the road to Zurich; it has a town-house, a public school, a paper-mill, and about 2000 inhabitants. 2. Cham, at the northern extremity of the lake, on the road from Zug to Lucern, has about 1000 inhabitants. 3. Menzingen, and about 2200 inhabitants. On the neighbouring hill of Gubel is a paper-mill and a representation of the defeat of the Protestants by the Roman Catholics in 1531, during the religious wars which followed the Reformation in Switzerland.

The constitution of the canton of Zug is a representative democracy. The people assemble in May every year in their respective communes, and appoint the members of the landrath, or legislative body, consisting of 162 members, who sit for one year, but are re-eligible. The canton is divided into six judicial districts or administrative departments; the whole canton is divided into 19 cantonal districts, and into 243 communes. The canton is divided into 6 sections, each of which contains a cantonal assembly. The criminal court is composed of 25 members taken from the commune. There is also a civil court for the whole canton, and inferior courts in every commune. Fornication is reckoned among other punishable misdemeanours. In all these small democracies the number of public functionaries is multiplied to an extent which seems to be an evil cut-off. For instead of making 500 the number of the population, which is done in order that all the citizens may in turn enjoy a brief period of power. The public revenue is supplied by both direct and indirect taxation.

The canton of Zug has kept itself one of the quietest among the political disturbances of Switzerland of the last half a century.

(Lesecche, Dictionnaire Géographique Statistique de la Suisse; Francini, Statistica della Svezia.)

domestic attractions; he was the most fortunate painter, perhaps, of his time. Lanzi criticizes his writings; terms them bombastic and pedantic, and says that instead of instruction they present a mere tissue of sterile and undigested speculations, and that one page of Vasari is worth more than all that Zucaro wrote.

(Vasari, Vite de Peintres, Sculpteurs, Vite de Pittori, c.; Walpole, Anecdotes of Painting, &c.; Lanzi, Storia Pict. &c.; Cen Bernuex, Dictionnaire Historico, &c.)

ZUCCHI, ANTONIO, an Italian painter, born at Venice in 1726. His father, Francesco Zucchi, was an engraver, and his mother, the daughter of Lewis, an Italian scientist, had been a pupil of Bernoulli; she learned painting under F. Fontebasso and J. Amigoni, obert Adam, the architect, when in Italy, engaged Zucchi to make drawings for him; and Zucchi travelled with him in the north of Europe. He accompanied him to this country, where he was much employed by Mr. Adam in the small fresco and painting:

He painted mythological subjects, ruins, and natures; his colouring was pleasing, but his style was periphrastic and merely ornamental. He executed some of the best classical compositions on the subject of the triumphs of the Empress Caterina, done in the year 1745, for the Emperor of Austria. He was twice married, and had three children.

ZUG, THE CANTON OF, one of the smallest cantons of the Swiss Confederation, is situated nearly in the north of the canton of Zurich, on the east and south by Schwyz, and on the west by Luzern and Aargau. It is about 14 miles long from east to west, and about 10 miles in its greatest width. It lies in the basin of the river Reuss, an affluent of the Aare, and its waters flow in a northern direction. The principal part of the lake of Zug occupies the centre of the canton; the southern part is in the territory of Schwyz.

The lake is a fine piece of water, about eight miles long, and between one and two miles wide, surrounded by high mountains, some districts of which, like a continuous orchard. There are also fine meadows, and the horned cattle are remarkably large and fine. Wine is made in several localities. The principal articles of exportation are dried fruit, kirsch-wasser, herring, and dried fish, and some of the vineyards have been converted into pasture-ground.

The origin of the lake of Zug is traced to the small lake of Ageri, which is separated by a mountain ridge from the lake of Zug, is surrounded by sand-hills, and has in its basin small hills, which are partly covered with woods.

The lake of Zug forms a large plain, between 25° and 28° 30' N. lat., and between 4° 15' and 8° E. long., and covers about 12,000 square miles, or about twice the extent of the county of York. Near the middle it is narrowed by a projecting peninsula, on the east point of which the town of Zug is built, which extends about 20 miles north, and is the seat of the cantonal library. The arsenal of Zug contains, among other curiosities, the banner of the canton, stained with the blood of the fallen, and supposed to have been taken at the battle of Bellinzona, fighting against the Milanese, in 1422.
shoals, and is called the Pampus. Not far from its western extremity the Y is joined from the south by a narrow river, the Sauce, which is the short channel by which the lake of Haarlem discharges its waters into the inlet.

[Haarlem, vol. xi, p. 520.]

The shores of the Zuider Zee are generally low. On its eastern side they are well defined, and on the south-east, in the part of it which is adjacent to the Gelderian frontier, is several feet of land above the level of the sea. But the western shores are very low, so that a great portion of the adjacent countries is defended from the encroachments of the sea by dikes. Along the eastern shores the sea has sufficient depth for vessels of moderate size, and in general is a fair port for large vessels. But along the western shores several shoals occur, the most extensive of which are near the Texel and at the entrance of the Y; and at low tides there is so little water in them, that the larger merchantmen were formerly obliged to discharge their cargoes outside before they could sail to Amsterdam. To obviate this disadvantage the North, or Helder Canal has been made, which begins at the Mars Diep, in the strait which divides Texel from the Helder. Near the village called the Helder a new breakwater, 1200 yards long, has been built, and is so extensive, and deep enough to allow ships of 600 tons burthen to lie close to the quays even in the greatest storms. The Helder Canal begins at this place, and extends southward to Alkmaar. A few miles south of Alkmaar it turns sharply to the west, and passes to the town of Amsterdam, which is about 7 miles southward to the Y, in which it terminates opposite the town of Amsterdam. This canal is capable of receiving the largest merchant-vessels, and the locks are so wide that ships of the line of 74 guns can pass. It is about 15 miles long, 220 feet deep, and the great work was begun in 1819, and completed in 1833.

According to the most antient accounts of three parts of Europe, which are derived from the Roman writers, the Zuider Zee did not exist, but its place was occupied by a low swampy marsh drained by the river Yssel. This river was not then, as it is now, considered an arm of the Rhine. But after the Roman general Claudius Draus, about twelve years before the Christian era, had caused a canal to be made from the Rhine to the Yssel, the depth of the water brought down by the Rhine was discharged by this canal into the Yssel. It does not appear that this change in the course of the rivers materially affected the low countries drained by the Yssel, as no change is recorded before the beginning of the thirteenth century. But in 1210 a great portion of the low country was inundated by the sea, after continued north-western gales, which broke down the dikes by which it was protected against the water. Before the inhabitants were able to repair the dikes the Franklin, one of the greatest towns which were still newer attacks of the sea, after the sea had retired, new inundations took place, which washed away the soft soil with which the country was covered, and rendered it impossible to do anything for the protection of those tracts which had been newly given to the sea. And the country has not been reclaimed since the year 1282, and gave to the Zuider Zee the form and depth which it still preserves.

Zurich is a Prussian town in the government of Frankfort and province of Brandenburg, situated in 52° 0' N. lat., and 13° 40' E. long., in a fertile plain at the distance of two miles and a half from the Oder, and 110 miles from Berlin. It is surrounded with a rampart and a moat, and has outside of the town a citadel, which is surrounded with its own wall and ditch. The town is well timbered, which is more the cause of the town. The public buildings and institutions are, one Lutheran and one Calvinist church, an orphan asylum, a school founded in 1710 by Sigismund Heinrich, a needle-maker; a royal school called the Paedagogium for children to many students. The number of inhabitants is about 5000, who have manufactories of wooden cloths, linen, dimity, stockings, hats, leather, starch, and powder: there are tanneries, breweries, brandy-distilleries, and vinegar-manufactory. The trade of this town is very considerable. It is particularly the inhabitants who produce very considerable quantities of fruit and hops, and at the distance of a league from the town have plantations, in a good soil and warm situation, 70 vineyards, which are the most northerly in Germany. The number of those flourishing in Northern Germany, the monks extended the cultivation of the vine to Bodelschwein and Schwerin, on the shores of the lakes; but these vineyards were abandoned when the monasteries disappeared.

[Geiler, Lehrbuch der Physiographie, Appendix, W. A. von Schlieben, Neueste Genieblize der Französischen Monarchie; Johann Hübner, Zeitungs Lexicon; Neues Geographisches Lexicon.)

ZUMBO, GAETANO GIULIO, a celebrated Italian artist, distinguished himself for his noble and coloured wax: he is said to have made a copy of the last Judgment by Michael Angelo in wax.

(Fiorillo, Geschicht der Malerey, vol. i.)

ZURBARAN, FRANCISCO, a very celebrated Spanish painter, was born at Seville, November 9th, 1598; he is called the Spanish Caravaggio. His parents, who were of the labouring class, soon were covered in young Francisco an ability to excel in painting, and they accordingly sent him to Seville to study. Juan de Rojas, Z. he made, WINAPI paintings under Mr. Zumbo. He made another great masterpiece, called "Zurbaran," which consists of a group of five figures in high relief, shewing various stages of decomposition of the human body after death. At one corner of this work he has put his portrait and inscribed under it his name as follows: "Juan de Rojas, Z. He made, WITH his own hand, this work."

Zurbaran's works are very numerous at Seville; there are several at Cordova and Guadalajara, and some at Castello and Penaranda. Out of Spain they are very few.
common, but Marshal Soult brought away some, and others have been sold and removed more recently. In the Spanish Museum in the Louvre there is a room devoted chiefly to the works of Zurbaran; there are in it, according to the catalogue, 91 pictures by him, but many of them are very indifferent. The sales force reached the Duke of Sutherland has a good specimen of his style. His works have as much nature and power as those of Caravage, and less vulgarity. The pictures from the life of San Pedro Nolasco at the Merced Calanda at Seville, though one of Zurbaran's earliest works, are among his best, they are remarkable for the skill with which he has managed he white draperies of the monastics.

(Cecco Bermudex. Diccionario Historico, etc. Koloff. Beschreibung der koniglichen Museen, etc. zu Paris.)

ZURICH, one of the large cantons of the Swiss Confederation, is bounded on the north partly by the canton of Schaffhausen, and partly by the grand-duchy of Baden, in the east by Thurgau and St. Gall; on the south by schwyz and Züg; and on the west by Aargau. The territory of Zürich lies in the basin of the Rhine, all its water courses flowing northwards into that river. The area of the canton is reckoned by Meyer of Knau of 32 German square miles, or about 764 English square miles. The population in 1837 was 231,571. There are almost no mountains, and the interior is more like a great valley, divided by brinks running perpendicular to the principal rivers of the canton, the Thur, the To se, the Stall, and the Limmat. The lake of Zürich, the eastern extremity of the cantons of Schwyz and St. Gall, is long and narrow; it runs through the middle of the canton, extending for about 25 miles from south to north-west; its breadth measures from one to two miles. The banks are strewn with thriving small towns and villages, especially on the side of Zürich; and the surrounding country, rising in gentle lopes on both sides, is planted with vineyards and orchards, interspersed with fields, exhibiting a most animated landscape, which contrasts with the distant view of the towers and ornamented walls of Zürich. There is a rapid clear stream, issues out of the lake at its north-east extremity, intersects the town of Zürich, and is joined by the Sihl, a river coming from the south, which has its source in the canton of Schwyz.

Agriculture is diligently attended to in the canton of Zürich, and the value of manure is well understood. The principal products are—corn, wine, fruit, and pulses. The wine is mostly white, and generally of an inferior kind, but in a few places it is grown on the same scale as the wine of Jura, Vaud, Neuchâtel, and Meillon, and the light coloured wine of Teufen, are as good as any in Switzerland. The corned cattle amounted, in 1836, to about 47,000 head; sheep to 33,000 head, only, besides 5500 goats. Considerable parts of the forested hills are prepared with forests, and some to the state, and some to the communists or to corporations.

More than one-eighth of the population of the canton is occupied in manufactures. The cotton and silk manufactures are by far the most important; they have been noticed under Switzerland (Trade and Manufactures). Zürich arises on an active trade, especially with Italy, and it contains several highly respectable mercantile and banking concerns.

Two dialects of the German Swiss are commonly spoken in the canton of Zürich; the written language is the high German, and is spoken by educated persons. The religion of the country, recognised as such by the constitution, is the Roman Catholic, established by Charlemburg and Augsburg. The number of the clergy is nearly 300, of whom 143 are incumbents of parishes. About 2000 Roman Catholics are scattered about various districts of the canton; they have a Benedictine convent at Rheinau on the Rhine; and a Benedictine convent at Rheinau on the Rhine.

The public revenue of the canton of Zürich amounts to between 1,100,000 and 1,200,000 Swiss livres. The Swiss army is worth one-half more than the French fleet, or fifteen pension sterling. The revenue is derived chiefly from the customs, the tax on property, the rents of land belonging to the state, and on post-office and other items. The expenditure is distributed under the following heads:—Civile administration, 178,000 Swiss livres; police, 95,490 livres; military, 122,000 livres; public worship or church, 182,154 livres; public instruction, 185,490 livres; roads and public buildings, 360,000 livres. There is a body of permanent gendarmerie composed of 108 men, chiefly that of the town of Zürich. The militia, which is the national force, consisting of all the men from 19 to 40 years of age, is organised after the same manner as in the other cantons of Switzerland. The contingent or select militia, which is made up every year of about 5000 men; the landwehr, which is next liable to take the field in case of emergency, is about the same number. By the actual constitution, which was sanctioned by the great majority of the people in 1831, and was afterwards revised in 1837, the canton of Zürich is a representative democracy; all citizens who have attained twenty years of age enjoy the elective franchise, except bankruptcy, parricidal, and immoral, and those who labour under an interdict. The canton is divided into 65 electoral circles, of which 18 are for the town of Zürich, and 62 for the country. The electoral circles return one deputy for every 1200 inhabitants. The Great Council or Legislature consists of 242 members, who must be at least 30 years of age, and of thirty-three are chosen by the Great Council itself to complete its number. By the constitution Zürich returns a greater proportion of deputies relatively to its population than the country districts, and this is the case in most of the larger cantons of Switzerland, where the chief amount of income is in the hands of the head town. The deputies are elected for years. The Council appoints the Executive Council, which consists of 19 men for six years, and is presided over by the burgemeister. The Great Council appoints also the members of the court of justice, consisting of 12 men, and those of the ecclesiastical council, which superintends the administration of the church, and is formed both of clerical and lay members. Besides the ecclesiastical council there is a synod or assembly of the clergy, which constitutes the supreme authority for spiritual and temporal matters, which meets at least once a year, and is presided over by the antistes or head pastor of the church of Zürich. The canton is divided for administrative purposes into eleven districts, having each its council for local purposes, whereof 13 or administrative Zürich and 62 for the country. The use of torture was abolished at Zürich by law in 1831.

Zürich, the head town of the canton, is pleasantly situated at the north-west extremity of the canton, and by the river Limmat into nearly equal parts; of which the one on the right bank is called the Grosser Stadt, and the other the Kleine Stadt. The Grosser Stadt is built on the slope of a hill called the Zürichberg; the Kleine Stadt lies on more even ground between the Limmat and the Sihl, just above the confluence of the two rivers. Both towns are surrounded by ramparts and ditches, with bastions and ravelins, but the works, being commande by the neighbouring heights, have been lately ordered to be converted into mostly narrow streets; the houses high, massive, and ancient looking, and the general appearance is that of a town of the Middle Ages. There are however some modern and handsome constructions, especially in the Kleine Stadt. The minister, or cathedrall, is the most striking object, and the towers is called the tower of Charlemagne, for it is said that that sovereign, during his German expeditions, resided some time in this spot, which was then beginning to be inhabited under the name of Zürich-Tor. The two remarkable buildings of Zürich are—the Frauenmünster, once a nunnery, built in the sixteenth century; the Prediger church; the church of St. Peter, with its handsome tower and clock; the town house; the orphan asy1um; the Wasserkirche, with the town library annexed to it; the new university; the Casino, or assembly-rooms; the Wollenberg tower and dungeon, in a small island in the middle of the river, where state prisoners were formerly confined; the arsenal; and the new police and guard house. The principal promenades are the Lindenhof, in the Gross
ZURITA, GERO NYMO, a distinguished Spanish historian, was born at Saragossa, on the 4th of December 1512. He studied at Alcala, under Hernan Nunez; in 1530 he was appointed chief of the municipalities. After a period he succeeded his father-in-law, Juan Gazias de Olivan, as fiscal in Madrid. In 1543 he was admitted into the supreme council of Castile, and sent on a mission to Germany. On his return to his native country in 1548, he was appointed by the states of Aragon, 1570, 3. chronicle: the kingdom, the first who filled the office, then his institute.

The duties of this appointment appear to have engaged his whole time from 1560 to 1567. An ordinance issued in his favour by Philip II, to all the priory and abbeys of his dominions, enjoining them to open their archives and communicate their most secret papers to Zurita. Thus authorized, the Coronists travelled almost everywhere, and collected a great number of important documents.

In 1567 Zurita was appointed private secretary to the king. In 1568 the grand inquisitor intrusted to his charge all the correspondence of the holy office. Towards the end of his life he contributed a large number of works, and retired to the Hieronymite convent of Saragossa. The continuation of his Annals of Aragon was the occupation of his declining years. He died in his convent, on the 3rd of November, 1581. His books he bequeathed to the Catholic Church, and many of them were taken possession of for the Escorial library.

The works of Zurita are:—1. 'Annales de la Corona de Aragon,' Saragossa, 1502-79; 2. 'Indices rerum ab An- gnasiae Regibus gestarum ab initis regni ad annum 1148.' Saragossa, 1587; 3. 'Historia de la historia en el reyno de Aragon, que contiene en quatro libros varios successos desde el 1512, hasta el 1580.' Saragossa, 1580; 4. 'Emmiendas y Advertencias en las coronicas de los rey de Castula que escribo don Leon de Ayala,' Saragossa, 1683.

Botterweck and Holtinger have collected separately in terms of the writings of Zurita. By a lucid exposition of the connection of events he has succeeded in developing the growth of the Aragonese constitution.

Zurnapa, the Chronicle Alexandrinum,' published by Ducange among the Byzantine historians. Some grammatical notes of Zurita on the 'Commentaries of Caesar,' Claudian, and the 'Antonine Itinerary' are preserved in MS. in the libraries of the University of Tournai, the Bibliotheque de la Sociedad de las Americas.

ZURNAH, the Arabian name, according to Beel of the Giraffe, of which, as far as present research has gone, there appears to be but one living species; no satisfactory evidence having been brought forward to prove that the Giraffe of Nubia, Senegal, and the Cape are significantly different.

Fossil Giraffes. Since the article GIRAFFE was written some highly interesting additions to the history of the animal have presented themselves.

Dr. Falconer and Captain Captalley have discovered in the tertiary formations of the Himalayan range jaws and portions of upper and lower jaws associated with the remains of Camelus, Hippopotamus (Hyper- ProtoDino of Falconer and Captalley), Anoplotherium, Sinotherium, Mastodon, &c.

The species of Giraffe, found upon considerable portions of the jaws and teeth, is identical in size and configuration with the Giraffe of the Cape, with which it has been compared at the College of Surgeons in London.

The second species of Giraffe is one-third smaller than
the existing species, but has the same characteristic long
and slender neck, as is proved by the fossil cervicial ver-
tebre, which, with all the characters of maturity, differ
from the corresponding vertebrae in the African or existing
species, in being one-third smaller, and in some slight va-
riations of configuration.

The former supposition, due to the researches of these ac-
complished and zealous officers, of the extension of a genus
supposed to be peculiarly African to the continent of
India, in the case of the Sewalik Hippopotamus, is now
paralleled by the discovery of the associated Giraffes.
As far as we know, this one Hippopotamus, as far as we
know, has more than one Giraffe; but there existed at least two species of both these genera
during the ancient period when the conditions of the Sue-
cisses had not, as we know, the same peculiarities. The
contemporaneous Strathera, Mastodons, and other
gigantic forms of Mammalia dependent for their food upon
the rich and teeming vegetable produce of the soil. Hip-
opotamis require deep rivers for their safe and comfort-
able mode, and Giraffes are especially organized to sub-
exist on a peculiar natural family of trees—the Acacias, which
confine them to plains or regions of moderate elevation.
But the fossil remains to which we have called attention occur more than 5000 feet up the loftiest range of moun-
tains in the world. The stromata of the lizards, which have now become famous from the abundance of these fossils are now narrow and rapid, hastening to pour
themselves into some tributary to the Ganges, and must
long have lost those characters which adapted them for
the marshy and stagnant localities which have a peculiarly
characteristic of the present altitude of the soil, and could
as little yield subsistence to Giraffes. When therefore
these now peculiarly African types of gigantic herbivorous
mammals, and some of the closely allied, the giraffe,
characteristic of the geographical character of the land was such as to have afforded the requi-
ses of the Hippopotamus and the acacia-groves for the
Giraffes.

ZUTPHEN, situated in 52° 8' N., lat. and 6° 12' E.
long., is an inland town, in the province of Gelderland,
in the kingdom of the Netherlands. It lies on the right
bank of the Zwin, which is the source of the Yssel, and
is traversed by the Berkel, which divides it into the New
and the Old towns, and falls into the Yssel. There is also
an extensive suburb, with many gardens and country-
houses. It is strongly fortified, and the ramparts, which
are planted with trees, afford a pleasant public walk.
The principal public buildings are, the great church,
an antient stately edifice, St. Eusebius's church, containing
the tombs of several dukes of Gelderland, and two other
churches, including the magnificent collegiate church of
deputies, and the SGravenhof, or count's palace. There
is a Latin school, a society of architecture and
drawing, a school of art, and a society for the study
of the natural history. There are 11,000 inhabitants, who have a
lively commission with Germany and the neighbour-
ing countries. In the war with Philip II., king of Spain,
Zutphen was besieged in 1572 by the Spaniards, who took it
by storm, and committed the most frightful excesses. It was
again besieged in 1575, by the city of Ghent, in which the
great scholar, Philip Sydney, was killed. Near Zutphen is the beautiful
country-seat of the king of the Netherlands, called the
Loo.

(Hassel, Handbuch, vol. ix. (The Netherlands); Stein's
Handbuch, edited by Hörmelchmann; Cannabach, Lehr-
buch.)

ZWINGLI, or ULRICH ZWINGLI, the reformer
of Switzerland, was born at Wildhaus in the Tobggenburg,
in January, 1484. His father was a substantial farmer.
Zwinglei, however, was so entirely against all ecclesiastic
whence he went to study philosophy at Vienna; on his
return to Basle he went through his theological studies
under Thomas Wytttenbach. He was ordained priest and
said his first mass in 1506. He was then appointed to the
parish of Glarus, head town of the canton of that
name. He applied himself strenuously to the study of the
Scriptures in the Hebrew and Greek texts, and that of
the early fathers of the church. He appears to have been early
impressed with a notion that all was not right in the go-
vernment and discipline of the church as then established,
and he communicated his doubts by letters to several
learned men, with whom he was acquainted. His life was
pure and exemplary, and he was much beloved by his
flock for his sermons; he inculcated the practice of Gospel
morality, avoiding so much as possible to speak of
the intercourse of saints, of images and relics, and of fasts
and pilgrimages. He was also one of the first among the
military contingent of Glarus to the wars in Italy, in
which the Swiss were then taking an active part, as aux-
iliaries to one or the other of the belligerents. Zwinglei
went to Milan when the Stuart was in that city, but
in intrigues and bribes of Cardinal Schinner, refused to
rally the treaty of peace with France agreed upon by most
of the cantons, and marched out to attack the French army
under Trivulzio, more than double their strength. They
were defeated at Magdeburg, 27th of July, 1515, and the
15th of September, 1515, lost one-half of their number,
but at the same time so crippled the French that they
were allowed to retire unmolested with their artillery
and their wounded.

On his return to Switzerland, Zwinglei wrote some strong
remonstrances to the governments of the various cantons,
entreaty them to put a stop to the practice of foreign
enlistment, and not to allow the blood of their countrymen
to be wasted for quarrels not their own. After having
spent some time at the court of the Emperor, in 1516,
preacher to the monastery of Einsiedlen. There, in the
very sanctuary of devotion, practices, pilgrimages,
indulgences, and vow offerings, Zwinglei preached
more than that he had done at Glarus, and in every one
of those things, entreaty his audience to seek forgiveness
through the merits of the Saviour alone, and not through
the intercession of the Virgin and other saints, and to
consult the Scriptures as the only safe rule in matters
of faith with the emperor, the cantons, and the Abbey,
whom he had known in Italy, and he warmly represented
to him as well as to the Bishop of Constance the urgent
necessity of a reform in the discipline of the church,
entreaty them and their brother prelates to take
the books into their own hands and see for themselves,
and to judge for themselves; the eyes began to be opened to the astounding corruption around them, should lose all respect for the church, and
the whole social and religious world be thrown into an-
archy. At this time Zwingli had not yet seen the Consti-
This shows that the cause of populism did not originate with Luther alone, but commenced sim-
aneously in different countries, where minds similarly
were not only unacquainted with one another, felt a
common impulse from general circumstances and from what
they saw of the church. Zwingli and the emperor
in 1518 the traffic in indulgences spread to Switzer-
land. Bernardin Samson, a Franciscan friar of the con-
vent of Milan, was commissioned by his superiors to sell indul-
gences in Switzerland. Samson, a vulgar ignorant
man, in his eagerness for customers went beyond the lax not-
tions of the times, according to which most people believed that
indulgences remitted the guilt as well as the penalty
of past offences, a notion unwarranted by the councils or
by the divines of the Roman church. Samson told the Swiss
mediators that by purchasing indulgences to a certain
amount they might obtain a sort of privilege or immunity
for future sins which they might happen to commit.
Samson however was opposed by Zwingli, who wrote a
book at the church council of Louvain in 1517 and refused
the friar admittance, being supported in this by the
abbot, and especially by Theobald, Baron of Geroldseck,
who was the voge or economical administrator of the
abbey. Zwingli then preached to the assembled pilgrims,
the absurdity of the whole business, and especially the
shocking abuse of them which was being made, exposing
the mercenary object of the friar, and laying the blame
not on the heads of the church, but on their subordinate
agents. Even Fugger, vicar of the Bishop of Samson, and forbade him, under some allegation of
informality, to sell his indulgences within his diocese.
Bul-
linger, the rector of Bremgarten, and a friend of Zwingli,
refused Samson admiration to his church. The friar how-
ever reaped a good harvest at Luzern, Bern, and other
places.

Vol. XXVII. — 5 N
In the mean time Zwingli had been invited by the chapter of the Gross Münster, or collegiate church of Zürich, to be their preacher, which offer he accepted and found no objection to preach anything but the word of God as it is in the Scriptures. On Samson making his appearance at Zürich, he found there his old antagonist, and was of course refused admission. So much for Zwingli, though he returned there, but carrying with him, according to the account of Stettler, in his Chronicle, about 800,000 crowns. This was in 1519.

Zwingli, from his opposition to the sale of indulgences, was led to investigate other questionable practices of the Roman Church. In the descent of the Gospels was corresponded on these matters with several men of learning in other parts of Switzerland; Henry Lovit, of Glarus, styled Graeurnus; Kopfbin, who Latinized his name into Capito, according to the fashion of the times; Haußenschmied, of Basle, called Oediamannus; Henry Bullinger of Brenngarten; Thomas Wyttunbach, of Bienne; and Berechtheud Haller, of Bern; all of whom preached against indulgences, and against the multiplicity of external forms in worship. They all insisted upon the propriety of reading prayers in the vernacular language of each country, and they recommended that religious instruction should be made clear, intelligible, and accessible to all. By degrees they were led on to gainsay the right assumed by the see of Rome to decide upon questions of ecclesiastical polity. Erasmus of Rotterdam, who was living at Basle, and who had gone along with them in exposing and ridiculing various superstitious practices and other clerical abuses, stopped short when his friends demanded a reform in the eclesiastical polity. They were not then catholic. His brother John was in Italy; his name was Anglerius.) The court of Rome, whose attention was engrossed by Luther's German schism, had hitherto taken little notice of the Swiss controversy, but now it began to threaten the innovators with excommunication. The bishop of Basle, having forfeited the protecting of the new doctrines, and the Mendicant orders laid charges of impiety and sedition against Zwingli before the magistrates of Zürich. Zwingli published his defence under the title of Apologiæ Crucis, in 1522, copies of which were rapidly sold. The eye of the see of Rome was fixed upon the town-hall, as a nest of the zealously and increasingly appearance against Zwingli; Luther had just been condemned at Worms as a heretic, and was obliged to conceal himself. But Zwingli lived in a republican country, where he had less to fear from pope or emperor.

In January 1523, the canton of Zürich appointed a conference to be held at the town-hall, to which all the ecclesiastics of the canton were invited, for the purpose of hearing the exposition of the new doctrines and the sentiments of their opponents. Zwingli published a list of articles to be discussed in the colloquy. As these form the main subject of the separation of the Swiss reformers, or Evangelicals, as they began to style themselves, from the church of Rome, I will quote the paragraphs, with the gloss on them of Dr. Zahn, if I have an error," said Zwingli, "to assert that the Gospel is nothing without the approbation of the church, and to value other instructions and traditions equally with those contained in the Gospel. The Gospel teaches us that the observances enjoined by the men do not avail to salvation. The mass is not a sacrifice, but a commemoration of the sacrifice of Jesus Christ. The power assumed by the pope and the bishops has no foundation in Scripture. God has not forbidden marriage to any class of Christians; the double to be united together in matrimony has become the cause of great licentiousness of manners. Confession made to a priest ought to be considered as an examination of the conscience, and not as an act which can be absoluted. To give absolution for money is simony. Holy Writ says, 'Let a man withdraw from a heretic.' God alone knows the judgment which He reserves for the dead; and as He has not been pleased to reveal it to us, we ought to refrain from indirect conjectures on the subject. The jurisdiction devolved by the law on the secular magistrates, to whom all Christians ought to submit themselves. No person ought to be molested, for his opinions; it is for the magistrates to stop the progress of those which tend to disturb the public tranquility."

On the day fixed for the conference, the Council of Two Hundred, presided over by the burgomaster, assembled in the town-hall, whither the ecclesiastics of the canton, Zwingli included, repaired, together with a great number of spectators. The bishop of Constance had seen Faber, his vicar-general, accompanied by several theologians. They had been sent by Emperor Charles V., investigating the motives which had induced the government to convok the assembly, for the sake of becoming enlightened by a public discussion on the questions which excited the church and unsettled the consciences of the reformers. But it seemed improbable that the coun-

trines of Zwingli and his friends as heretical, to state the arguments against them. Faber however declined entering upon particular points of controversy, but desisted on the necessity of union in the church, and of obedience to the magistrates. He then asked the magistrates, if they knew the Holy Spirit; on the evils of heresy, and on the audacity of turbulent men who excited contentions and schism. As to those who appeal to the Scriptures in the three languages," said he, "I reply that it is not sufficient to oppose the sacred writings, but that it is necessary to understand them. Now the gift of interpretation is not one which is given to all. I do not boast of possessing it: I am ignorant of Hebrew; I know little of Greek; and, though I am sufficiently versed in Latin, yet I do not pretend to be able to ordain or proclaim the precept of assuming the office of a judge on questions concerning salvation; these can only be decided by a general council, to whose decisions I shall submit without a murmur; and which will become all the more irrevocable when it will be seen that there is no excommunication of one church by another, that each church has the right to interpret the Bible for itself, that no one is able to teach us the rules of interpretation, that we must consult the church and the ancient fathers in order to discern the right meaning of the text. To this Zwingli replied, that if by the church Faber understood the popes and cardinals, the historical records of many of them showed that they could not have been enlightened by the Holy Spirit; that if he meant the councils, he was placing too much authority in them; and if he was forgetting how many of those assemblies had accused each other of bad faith and heresy. Even the fathers of the church, observed Zwingli, 'cannot be regarded as unerring guides, since they often do not agree among themselves.' Zwingli, therefore, was bound to have different opinions on important points.

There certainly is a church that cannot err, and is directed by the Holy Spirit. This church is composed of all the true believers united in the bonds of faith and charity; but for the identity of the church, this is the only church that can be formed by the union of the true believers, and has the rest of the churches, which have in their own, if it do not assemble with pomp, it does not issue its decrees after the manner of the kings of the earth; it has no temporal reign; it seeks neither honour nor dominion: to fulfill the will of God is the only care which it can be induced to undertake on the invocation of saints and other points in debate, but it was no more than a desultory conversation, as the two parties did not meet on common ground; and the remarks of Zwingli, though they were arguments drawn from Scripture; while Faber chose has from the decisions of the councils and the traditions of the church. At last the burgomaster dissolved the meeting, but the council remained assembled; and after some deliberation, Faber was permitted to come among them. He was convicted of heresy nor refuted, should continue to preach the Gospel as before; that the pastors of the town and territory of Zürich should ground their discourses on the words of Scripture alone, and that both parties should avoid all personal reflections and reprimands. The forms of worship remained unchanged for the present, mass continued to be said, the images remained, but more frequent and more scriptural sermons were preached for the instruction of the people. Some of the more impatient partisans of Faber, however, ran headlong down a large crucifix which stood at one of the gates of Zürich, the culprits were arrested and charged with sacrilege. Zwingli blamed them for committing an act of violent innovation without the authority of the magistrate. He said, 'If they could not be called sacrilegious, as images ought not to be objects of religious worship. This gave rise to much debate in the council, which at last convoked a second conference, for the clergy to decide whether the bishop of images was authorized by the Gospel, and whether the mass ought to be retained. This conference was held in October, 1523. About nine hundred persons were present, including most of the clergy of the canton of Zürich. The council had invited the other cantons and allies of the Confederation, as well as the university of Basle, to send their deputies, but Schaffhausen and St. Gall alone answered the call. Zwingli and his friend Leo Juden ex
plained and supported their theses, viz. that the worship of images was unscriptural, and that the mass was not a sacrifice. The prior of the Augustines, after much de-
sate discussion, and that he could not refute Zwingli unless he were allowed to quote the canon law. The con-
ference lasted three days, but was not productive of any new argument against the Reformers, who had full time to explain their doctrines and to produce a deep impression on the minds of the prelates, which, with the favour of the Council, closed the meeting, and adjourned its own decision to the following year.

During the interval the council applied to the bishops of Constance, Basle, and Coire, begging of them explicitly to declare whether they were disposed to support Zwingli and his doctrine. The bishop of Constance alone sent to the council an answer that the use of the mass, which however contained nothing more than the usual reasonings of the Canonists in favour of whatever had been before urged by the church. Zwingli wrote an answer in order of the council, condemning the use of images, the invocation of saints, the exhibition of relics in churches, and the ex voto offerings. At the beginning of 1524, the Great Council ordered all the pictures, altars, and ornaments to be removed from the churches, allowing those which were the gift of private individuals to be restored to them or their descendants. Thus Zürich was the first canton in Switzerland which openly embraced the principles of the Reformed Church, Basle, as part of Glarus and Appenzell, followed some years later. In January, 1525, the mass was finally abolished at Zürich; and on Easter Sunday of that year the Lord's Supper was celebrated according to the simple form suggested by Zwingli, and which is the same as that observed in the Reformed churches of Switzerland and France to this day.

The next thing was to provide for the instruction of the people, and to find funds for that purpose. The canton of Zürich, of which Zwingli was a member, was a very wealthy body: it had its own fiefs and jurisdictions, and was independent of the council. Zwingli reasoned with his brother canons on the propriety of allotting a part of the amount received for the purpose of education, and on the expediency of doing this of their own accord, without waiting for the lay power to interfere. A majority of the chapter having recognised either the justice or the prudence of concele-

sion, a convention was agreed, among the chapters and the council, by which the former resigned its regalia of feudal jurisdiction and immunities to the state, swearing allegiance to the council as its sovereign, retain-
ing at the same time the administration of its own revenues, or, what is nearly the same thing, appropriating to the salary of spiritual pastors for the town. These canons who were capable of performing pastoral functions should be employed as such, and those who were old and infirm should be relieved of their duties; and the churches and places were not to be filled up, and the revenues of their benefices were to be employed in founding professorships for the gratuitous instruction of the people. A small minority of five canons protested against the convention, alleging the authority of the pope; and, not choosing to subject themselves to the lay authority, they quitted Zürich and retired into the Roman Catholic cantons. The abbess of the Frauenmünster and her nuns followed the example of the chapter; and reserving pensions for themselves during life, they contributed to the maintenance of the clergy and the propinquitous villeges. The surplus revenue was employed to found a seminary for candidates for the clerical profession. The convicts of the mendicant orders were afterwards suppressed by order of the council, the aged and infirm monks were relieved from the care of hospitals, and the habit of one of the convents, and the others were placed in various trades and professions. The convent of the Dominicans was transformed into an hospital for the sick. The reformers Augustus was into an asylum for the destitute. In every instance the property of the church was not swallowed up by the treasury nor embezzled by grasping individuals. It was guaranteed by the state, and made into a distinct fund for the purposes of education, religion, and charity. Dignity and profit were respected, and a decent regard was observed towards the feelings and prejudices of the old occupants.

of secularization of church property, so very different from the system of spoliations and plunder pursued in other countries, then and in our own days, even by states calling themselves Roman Catholic, unless it be the fate of the Swiss reformation, for the other reformed cantons generally acted upon the same principle of honesty that Zwingli proclaimed and enforced at Zürich.

Zwingli was commissioned by the government to orga-
nize a system of religious instruction, and to awaken the intelligence of the age. He reformed the public schools, appointed new professors for the classical languages, and founded an academy for theological studies. He appointed Conrad Pellican, a native of the same place, wittenbroock, to the rectory of Zürich, and John Collins, of Luzern, to that of Greek: this was in 1526.

The Anabaptists, a fanatical sect, the wild offshoot of the Reformation, who among other vagaries wished to establish a community of goods and a commonwealth independent of magistrates or government, made their appearance in the canton of Zürich. Zwingli had several conferences with some of their leaders; he tried to con-
vince them of the impropriety and impracticability of their schemes, but all to no purpose: disturbances were ex-
icted, the Anabaptists, being warned by the Council, refused to submit; they stirred up the ignorant people to acts of violence, until the government was obliged to resort to measures of severity in order to restore tranquility.

Zwingli did not attend the conference held at Baden in Aargau, in 1528, in presence of the deputies of all the cantons, in which Eckius, chancellor of the university of Ingolstadt, challenged the theologians of the Reformation. The Council of Zürich, in which Zwingli had a majority, and there was a manifest intention of seizing his person and

condemning him as a heretic. Oecolampadius, who was less known and less obnoxious to the Romanists, undertook to defend the doctrines of the cantons being Roman Catholic, the majority of the Reformers, and of the Zürich church, and opposed the resolutions of Eckius and Faber, grand-vicar of the bishop of Constance, to the effect that Zwingli and his adher-
ents should be considered as heretics, and as such ex-
communicated, and it condemned all the Anabaptist doctrines, or worship, and forbade the sale of heretical books. The cantons of Bern, Zürich, Basle, Schaffhausen, Glarus, and Appenzell protested against this decision; but the Roman Catholic cantons began to act upon it, and arrested and turned to death, all several of the Reformed preachers within their territories.

At the beginning of 1529 Zwingli repaired to a con-
ference held at Bern, by order of the senate of that canton. He was attended by Oecolampadius, Bullinger, Collinus, Pellican, and many of the chief Zürich church officials at Strassburg. The conference lasted nineteen days, and as it was laid down as a preliminary principle that no argu-
ment would be admitted which was not grounded on a literal interpretation of the Scripture, the latest Reformed doctrines obtained the advantage over their opponents. The consequence was that the important canton of Bern publicly embraced the Reformation.

In September, 1529, Zwingli repaired with Oecolampa-
dius and others to Marburg to hold a conference with Luther and Melanchthon. They agreed upon the principal points of faith, and signed together fourteen articles, containing the essential doctrines of their common belief: they only differed upon the subject of the Eucharist. Zwingli, in his 'Commentary on True and False Religion,' had asserted that 'the outward symbols of the blood and body of Christ undergo no supernatural change in the Eucharist.' The grounds of this controversy between the Zürich church and the Church of Rome are examined under the heads Reformation and Sacraments. Zwingli and Luther, after much discussion, parted, still in controversy, but not in anger. Zwingli was averse from dogma-
ticism, and it did not enter into the views of the Church. In his 'Exposition of the Christian Faith,' which he addressed shortly before his death to King Francis I., while he admits the necessity of justification by faith for all those to whom the Gospel has been made known, he cast no reflections on the imperfect instruc-
tion against those who have not been acquainted with the Scripture, and he expresses his belief that 'all good men

5 N 2
who have fulfilled the laws engraved on their consciences, whatever age or country they may have lived in, will partake of eternal felicity.'

In the year 1531, after several angry and hostile demonstrations between the Roman Catholic and the Reformed cantons, war actually broke out. The Reformed cantons under the leadership of John Calvin in Geneva, the city and the church he had reformed, did not want to be subject to the secular power of which the bishop or governor was in charge. The Roman Catholics complained of the interference of Zurich with the territories of the Abbey of St. Gall, where the commissioners from the pope claimed liberty for theirmons. These grounds of the dispute were of a mixed nature, resulting from religious and political jealousy. The Catholic cantons broadly refused liberty of conscience to their citizens or subjects, on the plea that it was contrary to the doctrine of their church. Bern and Zürich came to the determination of stopping the supplies of provisions which Luzern and the forest cantons were in the habit of procuring from or through the territories of the other two, forbidding the citizens of the Western cantons from entering Bern or Zürich and enforcing a kind of blockade which was severely felt by the mountain cantons, which, being chiefly pastoral, depended for their supply of corn, salt, and other necessaries on the markets of their more prosperous neighbours. The town of Zug, Schwyz, Uri, and Unterwalden declared war against Zürich and Bern, and their troops advanced to Cappel, a village on the road from Zug to Zürich, and within the territory of the latter canton. The council of Zürich, which, however, had frequent disputes among themselves, did not expect to suffer an attack. A few hundred militia were posted at Cappel, and a body of about 2000 more were ordered to reinforce them in haste; and Zwingli received orders from the council to accompany and command the army, in the absence of the absent-minded general of the Reformed Churches of Switzerland, as distinct from that of Protestants, which applies more particularly to the German Reformed Churches, in consequence of the protest delivered to the Diet of Spires, in April, 1529. It ought to be observed however that the Lutherans were not alone in signing the protest, as many towns of Germany and the Landgrave of Hesse, whose tenants were like those of the Zwinglians or Sacramentarians, also joined in it; so that the affair was more like an attack of the Reformed Church, and not of the Lutheran Church, but applies in an historical sense to the German reformed churches in general. The Swiss had no participation in the protest, which was a political act of the German States. An account of these various denominations is given elsewhere of the cantons of Luzern and Bern, who, being in a state of war with each other, did not attack the mountain cantons.
ern, Schaffhausen, Mulhausen, Bienna, and St. Gall gave their ascent. The Evangelical portion of Appenzell was already agreed in their tenets with the state of Zürich. Notwithstanding all its alliances, Basle had an old formulary of its own, which did not materially differ from Bullinger's confession, and was only in the following century that it formally acknowledged the Helvetic confession of faith, as it was now called. This was accomplished in 1536, and the formulary was sent in their signatures. The churches of the intimation, those of Poland and Hungary, signed also the Helvetic Confession. The Reformed churches of France, through political and other reasons, drew out a confession of faith which was annexed to the book of sacrificial rites. (Vulliemin, Histoire de la Confédération Suisse, Continuation de Müller, Gloutz, et Holinger.) An abstract of the Helvetic confession of faith given in the appendix to the History of Switzerland by Mr. Mr. Z. The authorities on which the article is based are the Swiss churches.

On the abstruse topic of predestation, it affirms that 'God, out of his wisdom, has predestined or chosen some eternally, freely, of his own mere grace, and without regard for persons, the righteous whom he intends to save through Jesus Christ,' but at the same time it contains an apologetic judgment concerning the salvation of any individual or class; and it says that we must hope favorably of every one. 'If we hold communion with them, and assist in the processes of the church, he be ours and we his, we then have a tolerably certain proof that our names are written in the book of life.'

The appellation of Calvinists has occasioned some confusion with regard to the Reformed churches. Calvin, who acted at once as an ascetic and a professor, was a man of intense and elevated character, and the Reformation in Switzerland has its analogy in the Reformation in France. Calvin has had no influence over Switzerland, where the Reformation was established long before his time; and it is only by the Society for the Diffusion of Useful Knowledge that the Reformed churches of Switzerland have been called Calvinistical. [Calvin and Calvinism.]

ZWOLL. [OVERYssel]

ZYGZANIDÆ, a tribe of insects belonging to the order Lepidoptera, placed by Linnaeus with the Sphingidae on account of the resemblance of their antennae to those of that family. Lattreille divided them into two groups, according to the forms of the antennae, which in the one are simple, and in the other are branched. The type of each is a case, and at least in the males. Seasia and Zygaena are examples of the latter; Procis and Aglaope, of the latter.

The genus Zygaena includes some very beautiful insects, which, while they resemble moths in general aspect, fly during the day; and they are remarkable not only for the beauty of their colors, but for the brilliance of their wing margins. Their caterpillars have six feet, are olive-colored, and are not furnished with the coriaceous tubercle which those of the Sphingidae bear on the last ring of the body. Unlike the last-insect, these do not bury in the ground to undergo their metamorphosis, but are entirely viviparous. The seed, a single globule, is the only structure, and it is enclosed in a globe by the sepals of the flower, which is discharged in the shape of a winged seed when mature.

After conjugation the granules of endosperm, which form the spiral lines, appear, and collect into masses, which become the spores from which the future plant is reproduced. When the plant decays, these spores float about in the air, and, if deposited on the ground, are able to develop into plants by themselves. The young plant is developed from them. One remarkable phenomenon attending the liberation of these spores from the parent tube is the fact that many of them assume the habits and characters of insectivorous animals. Thus, when viewed under the microscope, the moving spores, or zoospores, as they are called, are generally of a green or yellow color, and of a more elongate form than the spores. Their motion through the water is somewhat different from that of the zoospores of Spirogyra. They are of a very small size, and that these are produced independent of the act of conjugation. Besides these organs, Mr. Hassall has described minutely a round body with a stellate structure, seated in the centre of the tubes of various species of Zygaena. This body he calls a cytoplast, but it seems to have another claim to such a designation than its having in the later stages of its development the appearance of some of the larger cytoplasts of higher plants. Mr. Hassall also describes a vascular structure existing between the granular masses which forms the base of the florets of the filaments of the Zygaena. This structure however is not

Z. zygaenae, with dark green filaments, parallelly joined, and the articulations with numerous arched spines. This is a very common species, and is found abundantly in the vicinity of Mr. Hally's observatory.
at all evident to other observers, and, as well as the deductions made with regard to its function, requires further investigation.

In the 10th volume of the Annals of ‘Natural History’ Mr. Hassall has described seventeen additional species of Zygnea, besides the three which produce their spores without conjugation. These have been chiefly found in ponds and ditches in Hertfordshire and Essex.

(Hooker's British Flora, vol. ii.; Hassall's papers in the 10th and 12th volumes of the Annals of Natural History.)

ZYGODACTYLLI, the term used by M. Temminck, M. Vielliot, and others to designate those perching birds which have their feet composed of two anterior and two posterior toes, the external toe of the two last mentioned being capable of a direction either forward or backward. The Parrots, Woodpeckers, Toucans, Cuckoos, &c. belong to this group, which forms the first tribe of the second order (Syllocelo) of M. Vielliot, and the fifth order of M. Temminck.

ZYGOPHYLLACEAE, a natural order of plants belonging to Lindley's Gynobasic group of polypetalous Exogens. Seventeen genera are referred to this order, and the number of species is not great. They are herbs, shrubs, and trees, having a very hard wood, and the branches often articulated at the joints. The leaves are opposite, and are furnished with stipules, are seldom simple, mostly unequally pinnated, and without dots. The flowers are hemispherical, regular; the calyx is divided into 4 or 5 pieces, with concave or convolute whorls; the petals are unequilateral, alternate with the segments of the calyx, and a little longer; during aestivation they are very short and scale-like; the stamens are double the number of the petals and dilated at the base, sometimes naked, sometimes placed on the back of a small scale and hypogynous; the ovary is simple, surrounded at the base with glands or a short spinous disk, more or less deeply furrowed with 4 or 5 cells; the ovules in each cell 2 or more, attached to the minor angle, pendulous or occasionally erect; the style is simple, usually with 4 or 5 furrows; the stigma is simple or with 4 or 6 lobes; the fruit is capsular, sometimes fleshy, 4 or 5 angles or wings bursting by 4 or 5 valves bearing the disseminules in the middle or into as many close cells, and the seeds are not so many in number as the ovules, and are either compressed and sebaceous when dry, or ovate and smooth with a thin herbaraceous integument; the embryo is green with a superior radicle, foliaceous cotyledon, and a whitish albumen of a horny and carnitious texture.

This order is nearly related to Oxalidaceae and Rutaceae; from the former however it is distinguished by a multitude of characters, and from the latter it is distinguished by its fruits being furnished with stipules, and being without dots. Lindley observes, 'With Layard's genus they ascend in the stamens springing from the back of an hypogynous scale, a structure well worth more attentive consideration than it has yet received: something analogous to it will be found in the genus Tribeasus.'

The great bulk of the species of this family are found distributed throughout the temperate regions of the globe; they are not, however, wanting in the tropics. The largest number are found in America, but the order has representatives throughout all the quarters of the earth, and even in New Holland. Many of the species are known as yielding timber, medicinal secretions, and ornamental plants. The following are the characters of the most important genera:

1. Leaves opposite.

**Tribulus** (from τρίβολος) : carpels 5, 1-celled, 1-seeded, indesicate, beset with prickles on the outside; style absent; 5 sepals, 5 petals, and 10 stamens.

Ehrenbergia (named after C. P. Ehrenberg, a celebrated German naturalist): capsule 10, 1-seeded, indesicate, crested.

Fagonia (in honour of Mr. Fagon, physician to Louis XIV.), and a patron of Adanson): the capsule sessile, 5-celled, 5-valved, and many-seeded; the style simple, and the base of the calyx dilated; the stigma single; the sepal 5; the petals 5; and the stamens 10.

Roperia (named after J. Roper, a German botanist, author of a monograph on the genus Euphorbiurn): capsule 4-styled, 4-valved, and 4-celled; the style and base of the calyx joints, and the base suppressed from 5 petals; the stigma single; the sepal 5; the petals 5; and the stamens 10.

Guaiacina, from Guaiac (a native name): capsule sub-stipitate, 5-angled, 5-valved, and 5-celled; from 2 or 3 2- or 3-celled from abortion; 10 stamens; 5 petals; 5 styles; and the seeds solitary in the cell.

2. Leaves alternate.

Biebersteinia (in honour of F. M. Bieberstein, a Russian botanist, author of 'Flora Tauro-Caucasia'): carpels 3, corollate at the base, 1-seeded; petals 5; sepals 5; stamens 10; styles 5, joined.

**Melianthus** (from μελις and ηνος, honey-flowers): capsule 4-lobed, with 4 cells, which are 1-seeded from abortion; calyx 5-cleft, unequal, the lower segment gibbous; petals 5; the stamens 4, of which 2 are connate; style single, crowned by a 4-cleft stigma.

The species of the genus Tribulus are diffuse herbaceous herbs with abruptly pinnate leaves and membranous stipules, with yellow or white flowers seated on axillary pedicels. This genus, with some others belonging to this natural order, was included by Jussieu in his order Rutaceae.

* T. cistoides, Cistus-like Caltrops, has leaves with 8 pairs of equal leaflets, which are silky beneath, with pedicles the length of the petioles. This plant is a native of South America and the West Indian Islands. It has large yellow flowers, resembling those of the rock-rose, which give or a pleasant fragrance. It is abundant about Kingston Jamaica, where it is called turkey-flower, and is cultivated in the gardens on account of the beauty of the flowers. Fowls are said to be fond of this plant, and it is supposed to fatten them, as well as to heighten their flavour.

* T. terrestris, Common Caltrops, has leaves with usual pairs of equal leaflets; the pedicles shorter than the pedicel and the carpels four-celled. This plant is found on the South, Europe, of Senegal, and of the Mauritius, in barren sandy places. In the South of Europe it is so abundant in the arable land of southe parts, that it is troublesome to the cattle on account of the angles running into their feet. The French give to this plant the name of La Croix de Chevalier. The other species of this genus are found in Egypt, North America, Africa, and the East Indies. All of them form pretty plants for cultivation.

**ZYGOSUS**

The seeds of the annual speci...
should be sown in a hotbed in spring, and the plants may be placed out on the open border in a warm sheltered situation, about the middle of May. The perennial species may be propagated either by cuttings or seeds, and will grow very well in a mixture of loam and peat.

In cultivation they can only be propagated by seed. It is a native of Syria and parts of the autumn in some rich light soil, and then placed in a frame, or the winter. In the following spring they may be placed in pots for the greenhouse, or in the open border. The shrubby species do not usually live more than three or four years.

There are two species of *Riparia*, both of them natives of New Holland. They are decumbent shrubs with small yellow flowers. They will grow in a soil composed of loam, peat, and sand, and cuttings will root freely when planted in sand under a hand-glass.

*Zygophyllina*, the Bean-Caper, is the most extensive genus of the order, comprising about twenty-seven species. They are either herbs or shrubs, with membranous or plicate leaves, or pinnate leaves, with red, white, or yellow flowers with a dark base.

*Z. simplicifolium* has simple sessile, cylindrical leaves. It is native of Egypt and Arabia, and frequently met with in the deserts of those countries. It has yellow flowers, and is called in Arabia *Germad*: it is esteemed a good remedy in diseases of the eyes, and the bruised leaves mixed with water are used for this purpose.

*Z. tubago*, Common Bean-Caper, has stalked leaves, obovate leaflets, erect pedicels, a smooth calyx, and unlobed petals. It is a native of Syria and other parts of the Arabian Peninsula. It has yellow petals of a copper-brick colour at their base. This plant is a common herbaceous perennial in our gardens, and was cultivated in Great Britain by Gerard as early as 1596. This plant is supposed by some writers to be the *Telephium* of Dioscorides.

*Z. fistulosa*, Petit Bean-Caper, has stalked leaves, obovate leaflets, nodding flowers, a downy calyx, and cut reflexed petals. It is a native of the Cape of Good Hope, and has orange-yellow petals with a purple spot at the base. The plant gives out a strong foxy-like scent, which renders the house in which it is grown very offensive, and on this account it is seldom grown. It was introduced by Mr. Marson in 1790.

*Z. coccineum*, Scarlet-flowered Bean-Caper, has stalked leaves; cylindrical, fleshy, smooth leaflets; erect pedicels; acuminate petals; and cylindrical capsules. This plant is a native of the deserts of Egypt and other parts of North America. Although abundant, all kinds of cattle and even camels refuse to touch it.

In the cultivation of these plants, the perennial species may be propagated by cuttings, which will root freely in a pot of sand under a hand-glass. When the plants are grown, they will thrive in a soil composed of loam and peat and sand. The annual species may be propagated by seeds sown in pots of the same kind of soil, and placed in a hotbed. The common Bean-Caper is the only species that will grow in the open air. It should be planted in a dry situation in a light soil. It can however be only propagated by seeds, which are only occasionally ripened in this country. The seeds should be sown in a pot and placed in a frame, and when the plants are four inches high they should be planted out in an open border.

There are six species of the genus of *Guaiacum*, five of which are trees. They are remarkable for the hardness of their wood, and have usually blue flowers.

*G. officinale*, Lignum-vitae, or Guniaecum, has leaves with two pairs of obovate or oval blunt leaflets; twin peduncles, and 2-celled fruit. This plant attains a height of about 30 feet, and is a native of Jamaica and St. Domingo. The wood is exceedingly hard, and is known in England under the names of Brazil-wood and Lignum-vitae. It is much used in medicine. [*Guaiacum officinale*].

*G. sanctum*, Holy Lignum-vitae, has leaves with five or seven pairs of oval, blunt, mucronate leaflets; the petals are orange-yellow, the pedicels fringed; the capsule 5-celled. It is a native of South America, and is abundant in St. Domingo, New Mexico, and Brazil. This tree attains a height of about 20 feet, and, according to Hernandez, has blue wood. It is called in some of the West India Islands Bastard Lignum-vitae. It has also been used in medicine, in the same diseases as the *G. officinale*, but more especially for syphilitic disease.

*G. arboreum* has leaves with from seven to fourteen pairs of oval, oblong, blunt leaflets, which are unequal at the base, and are usually alternate; and the pedicels and branchlets somewhat pubescent. It is a native of Carthageana, Guadaloupe, and Cumania. It was first described by Jacquin under the name of *Zygophyllum arboreum*. This tree is called by the natives of Cumania *Guai-a-cum*, which is in fact the name of all hard woods among them. This tree is one of the largest and handsomest of the order, attaining the height of 40 feet, and terminating in a beautiful head of branches.

In cultivating the species of *Guaiacum*, the ripened cuttings, if taken off at a joint, will root, and may be planted in a pot of sand under a hand-glass, which should be exposed to the influence of heat. Every part of these plants is brittle, and should be transplanted when the fibres are not broken.

The species of *Biebersteinia* are perennial herbs, beset with glandular hairs and having unequally pinnate leaves. There are two species: the one sweet-scented, a native of the Altai Mountains; the other a native of various districts of Persia.

The species of *Melianthus*, Honey-flower, are shrubs with unequally pinnate leaves, having a strong odour when bruised, and racemes of brown or yellow flowers.

*Melianthus major*, Great Honey-flower, has glaucous leaves, smooth on both surfaces, with large stipules joined to the petiole. Like the two remaining species, *M. minor* and *M. comosus*, this is a native of the Cape of Good Hope. All three species are shrubs, and attain a height of from four to six feet. They will thrive well in any light soil, and may be propagated by cuttings, or by suckers, which they throw out abundantly from the root. *M. major* may be grown in the open air against the wall, but it requires a mat in the winter.
